AMERICAN BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., JANUARY 3, 1901.

FORTY-FIRST YEAR
No. 1.

WEEKLY

MR. GASTON BONNIER,
*President of the International Bee-Keepers' Congress,
Held in Paris, Sept. 10, 11 and 12, 1900.*

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & CO.

118 Michigan St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, \$1.50 a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec 00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

Reformed Spelling.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Society and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th 1899 Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year, both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

YELLOW OR WHITE

Sweet Clover Seed

Free as a Premium

For Sending us One New Subscriber for a Year.

There has been so much written about both the white and the yellow variety of sweet clover, that we will simply say here that if one of our present regular subscribers will send us \$1 with a new name for next year (1901), we will send the new subscriber the balance of this year's (1900) numbers free, and mail, postpaid, to the one sending the new name and the dollar, either one pound of yellow sweet clover seed, or two pounds of the white sweet clover. This is a good chance to get a start of both kinds of these honey clovers. Better send two new subscribers (with \$2.00) and get the three pounds of seed. Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO, ILL.

BEST Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough the Alfalfa extracted.

BASSWOOD HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Either Alfalfa or Basswood Honey:

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are boxt. This is all

ABSOLUTELY PURE BEES' HONEY,

The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:

I've just sampled the honey you sent, and it's prime. Thank you. I feel that I'm something of a heretic, to sell several thousand pounds of honey of my own production and then buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drink, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honeys of more market flavor, according to my taste. C. C. MILLER.
McHenry Co., Ill.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 THE OLDEST BEE-PAPER IN AMERICA

41st YEAR.

CHICAGO, ILL., JANUARY 3, 1901.

No. 1.

Editorial.

1901—Volume XLII.—The first year of the new century is here—the 20th century. The first number of the 41st volume of the American Bee Journal is also here. Tho the past century was one of wonderful improvements and developments, we suppose this new century we are just entering upon will be still more wonderful. That hardly seems possible, and yet it doubtless will be true.

But what of the old American Bee Journal in this 20th century? It also must keep step with the progressive spirit of this rapidly advancing age. And it will do so. We need not make any promises for the future to those who have been reading the old American Bee Journal during the past 40 or more, or even less, years. We mean to keep its standard up hereafter as we have tried to do in the past. We realize that this we can not do alone—we must have the hearty and continued support and encouragement of the bee-keepers themselves. We believe we will have it—at least we will endeavor to merit it.

We can all, then, look forward to the coming years with a strong faith and a high hope, realizing that in a united effort for the right we shall be successful in all that is worthy and true.

The Uter vs. Uter Case in New York State, which has been referred to in these columns several times the past few months, came to trial again, and was decided in favor of the bee-keeper, on Dec. 19th.

Mr. O. L. Hershiser, superintendent of the apianian exhibit at the Pan-American Exposition, being present and assisting during the trial, the following account written by him will be read with great satisfaction by all, and particularly by the members of the National Bee-keepers' Association, whose money helped their fellow member to win his case:

MY DEAR MR. YORK:—I enclose you newspaper clippings concerning the now famous case of Uter vs. Uter, and will request that remaining papers containing accounts of the case be forwarded to you by the publishers. In the meantime, let me tell you so you will have no dismal apprehensions concerning the result of the litigation, that the bees were entirely exonerated of the charge of mischief as complained of. The case occupied over two days, the jury being nearly all drawn on Monday afternoon, and the jury's verdict brought in at about dusk on Wednesday evening.

For a case involving such insignificant damages, I've seen nothing that has created so much interest to lawyers and sensation to the people, in many a day, as did this case. It seemed to be the only subject of conversation

for the people in the hotels, railway stations and stores, and by groups of people on the streets. Besides local witnesses, the plaintiff had Mr. Banes—a fruit-grower of New Hampshire; and the defense, besides local witnesses, had several fruit-growers and apiarists from New Jersey, A. L. and E. R. Root from Ohio, Frank Benton from Washington, Mr. Marks from this State, and your humble servant as counsel and witness.

I understand the jury's first ballot was 10 votes to 2 blanks for no cause of action, which was immediately made unanimous for no cause of action. They were out scarcely five minutes. Was not that a complete victory?

Too much credit can not be given the just judge for his fair and impartial attitude and rulings on every disputed point, and for the great learning and ability of Messrs. Bacon & Merritt. And while passing, I desire that you know that learned and astute counsel were opposed to us in the persons of Messrs. F. V. Sanford and N. M. Kaine, both of whom are scholarly and gentlemanly members of the legal fraternity; and while they brought to bear all their scholarly attainments and legal acumen in this very bitterly contested case, I think that all on the opposite side will agree that they were treated in a gentlemanly and dignified manner.

Of course, you will observe that the scene of of this fight was in the village of Amity, which, to say the least, was very ironical; that, metaphorically speaking, one brother sought to kill or "do up" the other, and that this fratricide might be accomplished according to ancient usage, as recorded in Holy Writ. Kaine was brought in to assist one of the brothers in his fell purpose. However, the plaintiff would not be disposed of in this summary manner, and knowing of a firm of distinguished legal gentlemen, who, he said, *wereth their Banes*, he enlisted them in his behalf. These lawyers were Bent on (Benton) going to the Root of the matter, and, accordingly, sent for certain gentlemen from Washington and Ohio to assist them in getting down to first principles. The utter absurdity of the plaintiff's claims were made apparent to all observers, after the gentleman from Champaign had made Marks of his witnesses, by proving to the jury that in their claims that bees puncture peaches they were simply "talking thru their hats." And now that it has been judicially settled, that the claims of the plaintiff were too utterly Uter, I think we are justified in believing that peace will reign in Amity again.

Yours truly,
OREL L. HERSHISER.

From the clippings kindly sent us by Mr. Hershiser, we take these paragraphs, the newspaper in which they appeared being the Middletown (N. Y.) Daily Argus:

The case was opened for the plaintiff by Mr. Sanford. He said he asked only \$100 damages; that the case was not one which charged that peaches and trees had been destroyed by stinging. He claimed about as follows: The two Uters lived near Amity, in the town of Warwick. One raises peaches, the other a keeper of bees. William had 1,000 peach trees. Forty rods from one of his orchards are several hundred hives belonging to his brother. The bees from these hives acquired the habit of flying over to the orchard and "puncturing" his peaches, sucking the fruit, and making great quantities of it unfit for market. The juice trickling from the fruit would form a substance about the branches of

the trees, which, in time, destroyed the branches, and in time 49 trees were totally destroyed.

Wm. H. Uter, the plaintiff, was the first witness. This is the substance of his testimony: On July 5th last he walked into his orchard and noticed that there were many bees in his peach-trees. Every day after that the bees began to get thicker and thicker. He counted as many as 14 bees on a peach, and saw so many others on other peaches that he couldn't count them. He watched their operations. A single bee would come up to the peach, walk all around it, pick out a good spot, and put its nose in. Then it would wiggle its head one way and then it would wiggle it another. Then it would stand upon its feet and pull out its nose. Then another bee would come and find the hole. Then a third and fourth, and a whole lot of bees would come to that peach, and in less than a week the peach would die.

This is the way he found out that the bees were from his brother's hives: He built a box and put flour in it. Then by another contrivance he caught a lot of the bees on his peaches, put them in the flour-box, and when they had become white he permitted them to escape. Then he followed their line of flight, and in most cases they went direct to his brother's hives.

Next week we hope to have a further report on this celebrated case.

Clarifying of Wax.—It is a good thing to have the same thing viewed by many eyes, thereby reaching it from all sides. Regarding the clarifying of wax, the following kind note is received:

MY DEAR MR. YORK:—Haven't you made a little mistake in your editorial answer to Mr. Hill about the cooling of wax? The real truth is, that the time taken in the cooling of the wax makes no difference whatever—it is in the length of time it remains in a melted condition. The effect on color will be exactly the same if the wax should be slightly heating instead of cooling all the time it remains melted. And I can not conceive how you could possibly give the meaning you did to the quotation you made from Mr. Hill.

O. O. POPPLETON.

Decidedly Mr. Poppleton is correct, that the thing that makes a difference in the clarifying of the wax is the "length of time it remains in a melted condition," altho it is doubtful if any one has expressed the idea in that exact form before. But is it strictly correct to say that "the time taken in the cooling of the wax makes no difference whatever"? It is true that after the temperature of the wax has come down to the melting-point, it makes no difference whether it is ten seconds or ten years in getting down to the temperature of the surrounding atmosphere, but it does make a difference as to the time of the cooling of the wax down to about 145 degrees, just because the longer time it takes in cooling down to that point the longer time it is in the undesirable melted condition.

Having agreed that slow cooling is not nec-

the thing desired, but only desirable because it leads to the right condition, the practical question comes, Is it better to say to a beginner, "You must cool your wax slowly" or, "You must keep your wax a long time in a melted condition"? If he is told to cool his wax slowly, it is about certain that he will keep it a long time in a proper condition for the foreign particles to settle; at any rate, if any one has been misled by such a direction, it has not come to light.

Suppose, however, we try to be more exact, and say, "Your wax must remain a long time in a melted condition." One can easily fancy him saying, "Well, it will remain in a melted condition if I keep it hot, and I can just as well leave it on the stove half a day." So it remains "in a melted condition" for half a day—not only in a melted condition, but at so high a temperature that the particles are kept constantly in motion, and there is no chance for impurities to settle; and then it is taken off and allowed to cool rapidly, with the result that impurities are mixt all thru.

The best of all would be a full explanation.

Since the foregoing was written, the Bee-Keepers' Review has come to hand, and Editor Hutchinson says:

"The trouble with Bro. York's argument, as I understand him, is that he is confusing purity, or freedom from dirt, with that of color.... That is, he assumes that the dark color results from the presence of dirt, ... time and again have I seen the brightest, yellowest wax, fairly loaded with particles of dirt. If kept liquid a long time these particles settle to the bottom, but the color of the wax is not changed one iota."

There is no desire whatever to deny that two specimens of wax, entirely free from impurities may be very different in color. But it is also true that a very large part of the beeswax thrown upon the market is of the kind he mentions "fairly loaded with dirt." Now does Mr. Hutchinson mean to tell us that that dirt is of the same bright color as the wax when it is cleansed? Does a cake of it look just the same after cleansing as before? If the answer is in the affirmative, then there is something exceptional about the color of dirt in his locality. If a white handkerchief is covered with soot, we don't say it is white, but black.

Reformed Spelling. A correspondent writes that he would be a subscriber for life if it were not for the spelling which follows the rule, "A change of and of final to i when so pronounced, as in *banded* (look), etc., unless the accents the preceding sound, as in *chafed*, etc." He thinks until our lexicographers change the rule that makes the past tense and perfect participle of regular verbs end in *ed* there should be no change, and that it is confusing to children who are learning to spell to read this journal.

It would be hardly worth while to refer to the matter except for some who are recent subscribers. To them some explanation is due for departing from the general custom. This departure is not a whim of the American Bee Journal, not of a number of illiterate people. It is because our lexicographers, the ablest and best lexicographers of the world, have changed the spelling a fact of which our correspondent does not seem to be aware. If he will turn to page xvi of the Standard Dictionary, he will find the matter treated somewhat extensively. The change is endorsed by

the Philological Societies of England and America, and the Modern Language Association of America, the members of which include most of the recognized authority in linguistic science in England and America among them Hon. Wm. T. Harris, LL. D., who for years has been the United States Commissioner of Education, and the late very able Max Muller, of England, with professors from leading colleges in both countries. There is no law compelling people to obey these rules, no more than there is to compel people to talk good English, but reforms having such strong arguments in their favor, and urged by such high authorities, will surely prevail in the end, and it is the part of wisdom promptly to fall in with them.

If the father and grandfather of our correspondent had been of his mind, very poor would have been his chances for much modern literature, for they would not have allowed him to read a book that did not continue the spelling to which they had first been accustomed, such as honour, labour, Atlantic, arctic, etc.

Weekly Budget

MR. THOMAS G. NEWMAN, for so many years editor of this journal, and also general manager of the National Bee-Keepers' Union (a year ago united with the National Association), has this personal paragraph in the issue of his Philological Journal for Dec. 22, 1900:

The editor, in response to many requests for a public statement concerning his vision, would say that his health is much improved, but his sight has not yet returned sufficiently to allow him to read or write. This condition has prevailed now for more than a year, tho he has been taking daily magnetic or mental treatments the whole time, but he feels sure that full-sight would soon return, if he could take a much-needed rest, the optic nerves being only partially paralyzed, thru excessive strain. Mrs. Newman is also much in need of rest, after the extra labor and care of the past year.

THOMAS G. NEWMAN.

Mr. Newman's many old friends will all unite in the hope that he may soon have that necessary rest so that his eyes may recover. Also that Mrs. Newman may join him in the vacation.

MR. DADANT'S PARIS CREDENTIALS, which he mentions in his article this week, read as follows:

MR. C. P. DADANT.

Dear Sir:—I am pleased to inform you that the Board of Directors of the National Bee-Keepers' Association, thru its chairman, Mr. E. T. Abbott, has authorized me to present you this certificate of credentials, appointing you as their delegate to the International Congress of bee-keepers at Paris, or at any other meeting of bee-keepers which you may be able to attend during your trip abroad. On behalf of the Association, I desire to say that we feel that we have in you the person of all others the best fitted to represent American bee-keepers in Europe. Your large experience, covering many years of successful management with bees; your thorough acquaintance with all the latest methods and developments in use in this country and in Europe; your familiarity with the French language and customs, all these, and more, especially if you for the position, and will entitle you to a degree of respect that could be accorded to almost no one else. Altho a native of France,

we still consider you a typical American bee-keeper in every respect; and we desire you to convey to European bee-keepers our hearty good wishes, love and respect. We feel that we owe to dear old France a debt of gratitude for sending two of her best sons to America; and in sending one of them back to represent us, we bespeak for him a reception such as could be accorded to no other American bee-keeper a man whom we are proud to honor, and who, in connection with his venerable father, has done much to advance the pursuit in this country and in Europe.

Yours very respectfully,
FRANK C. COVY, President.
DR. A. B. MASOX, Secretary.

MR. FRED W. MUTH, of Hamilton Co., Ohio, with his friend, Mr. Hauk, made us a very pleasant call recently. They were on their way to visit among some of the manufacturers of bee-keepers' supplies. Mr. Muth having been an employee of Mr. C. H. W. Weber, of Cincinnati, for nearly two years past. Mr. Weber is well known to our readers as a dealer in honey and bee-keepers' supplies. Mr. Muth is a son of the late Chas. F. Muth, who did such a large honey-business in Cincinnati for so many years.

MR. W. A. PRYAL, of San Francisco Co., Calif., writing us Dec. 7th, said:

"The winter here is something fine, tho we are having slight fogs in the morning. These latter are said to be beneficial in warding off the cold weather, tho, to tell the truth, I think it is cold enough as it is—it is one of those cold spells that is full of dampness, the dampness being worse than dry cold. At any rate, all kinds of flowers, viz.: roses, geraniums, fuchsias, heliotropes, potato-vines, calla lilies, etc., are in bloom as if it were summer. The other day I took a little trip across the bay with some friends from Chicago, and visited Alameda, Oakland, and Berkeley. The day was a charming one, and the gardens and all landscape were arrayed in their best winter garb. The sun was so hot that none of us could wear wraps or overcoats. The Chicago folks were charmed with the climate and the cities they visited—the climate just delighted them.

"So far the whole State has been visited by cold rains, and it may be fairly expected that a liberal amount is yet to come. This will make the coming season a bountiful one. Still, it is yet too early to count one's chickens."

MR. GASTON BONNIER, whose portrait graces our first page this week, was president of the International Congress of bee-keepers at Paris, held during the World's Fair there last September, which is referred to by Mr. Dadant on another page. He was born in 1853. Being a cousin of the noted French apiarist, George DeLayens, he helped him in his young days in making experiments on the size of hives at different altitudes. In 1873 he entered the Superior Normal School, where he was first student, then professor. In 1887 he was appointed professor of botany at the Sorbonne (University of Paris), and in 1897 was elected a member of the Academy of Sciences of Paris.

Without going into the details of works published by Mr. Bonnier, and of experimental demonstrations due him, we will only mention the following works: In 1879, "The Nectaries," an anatomical and physiological description of the nectar-producing organs in plants; in 1887, the "New Flora," in which are indicated the plants visited by bees; and in 1898, the "ours Complet d'Apiculture."

These publications all have a direct bearing upon bee-culture.

Convention Proceedings.

Report of the Proceedings of the 31st Annual Convention of the National Bee-Keepers' Association, held at Chicago, Ill., Aug. 28, 29 and 30, 1900.

BY DR. A. B. MASON, SEC.

(Continued from page 821.)

FEEDING BEES RIGHT OUTDOORS.

Suppose your colonies were away from other bees, wouldn't it be safe to feed right outdoors to them, and let them carry it in?

Mr. Atkin—No.

Mr. Fixter—I have fed by placing the feeder on top of the colony I wish to feed in the evening about sundown, and by morning they would have it all taken down. Put in the syrup lukewarm.

Mr. Wood—I have had experience in feeding; after the bees are all thru breeding is the best time to feed; then feed all at once. If it is cool weather warm the food. Confine the bees to the combs they can cover, don't let them scatter, put the feed on top, and keep them warm.

FEEDING SUGAR SYRUP TO BEES.

Mr. Moore—Is there any particular danger in feeding granulated sugar from its solidifying in the combs? How can that be prevented?

Mr. Root—We never have any trouble, and our scheme is always to feed syrup thin, about half sugar and half water. If you make it a third water and two-thirds sugar you are liable to have some sugar solidify; you can avoid it a good deal by putting in water or some sort of acid. I think it is better to make it thin.

Dr. Mason—By adding honey you never have that granulation.

Pres. Root—You want to make it thin; make it about half and half; if you make it thin enough it won't granulate.

A Member—How early do you feed it?

Pres. Root—In September and October, in our locality, when the days are warm.

Dr. Mason—If you use that much water the bees will have a great deal of work to do.

Mr. Fixter—Take 15 pounds of syrup, by the time that is in the cells, when you have two parts sugar and one water, you have over 10 pounds of food left.

Pres. Root—You have to figure according to that when you feed that thin syrup.

Mr. Fixter—I have tried that, and weighed the hives before the bees were fed, and weighed them afterwards.

Mr. Green—Don't you have trouble in feeding this thin food rather slow?

Mr. Fixter—I ask Mr. Root in feeding this thin syrup and feeding it rather slowly (as I supposed he would have to), if he did not have trouble with getting the bees started to brood-rearing.

Mr. Root—Sometimes we feed 10 or 15 pounds at a time. The main idea in feeding thin syrup is to have the bees convert that syrup into honey.

Mr. Green—Sometimes it becomes necessary to feed bees in rather cold weather, and at such a time we must either mix it with honey, as has been suggested, or boil with tartaric acid and feed it then at a proper consistency, nearly the consistency of honey, and feed it rapidly.

Dr. Mason—If I understand you correctly, I think I have learned something, Mr. President. You say, "The main idea in feeding thin syrup is to have the bees convert that syrup into honey." By adding one-half water do the bees make the sugar syrup into honey? Is that so?

Pres. Root—I want to qualify that a little.

Dr. Mason—I guess you would better.

Pres. Root—in making it thin, one-half sugar and one-half water, the bees have an opportunity to invert it. Prof. Cook calls it "digest." If you feed it too thick they won't digest it and convert it into honey.

Mr. Abbott—I want to offer my protest so that the stenographer will be sure to get it, and the bee-keepers as-

sembled will be sure to understand it; that you can't feed sugar-syrup of any kind, to any kind of bees, and have it converted into honey [Applause], Prof. Cook to the contrary notwithstanding.

Pres. Root—What I mean by that is, it is not the same you get from flowers. What I mean by honey—real honey—is nectar from flowers stored by the bees in the combs and converted into honey; but nectar in cane-syrup is a good deal like we feed. What I am speaking of now is chemical honey, and not commercial honey.

Mr. Abbott—Either chemical or commercial honey. If you feed them cane-syrup you reap cane-sugar when you eat it.

Pres. Root—It will be inverted, tho.

Mr. Abbott—No, it won't be inverted; it will simply be cane-sugar.

Pres. Root—Where is Prof. Gillette?

Mr. Taylor—There seems to be quite an issue between Mr. Cowan in his paper and Mr. Abbott.

Pres. Root—Mr. Abbott speaks of chemical honey or commercial honey. I don't care whether they have nectar from flowers or sugar-cane; if you give them time enough they will convert it into honey.

Mr. Moore—I will have to enter an emphatic protest against the use of this term "chemical honey." You might as well say "glucose honey;" it is the same thing in the eyes of the public. I have handled a family trade for 15 years, and I am *red hot* on the subject, and lots of people have said to me, "Do you feed your bees sugar to make honey?" I say even a bee doesn't make honey; she gathers honey from the flowers. You can't give it to people in this scientific way; if you do they won't understand it. I tell them bee-keepers don't practice that sort of thing. First, it doesn't pay us. I state here, you can take lots of bees and produce honey cheaper than you can get it from sugar-syrup and other things. I tell them more than that, you can't get your sugar-syrup into the combs; if you got it into the combs it wouldn't be honey—it would be sugar-syrup in the combs; it wouldn't pay. I am protesting against using terms that are misleading to the people who won't understand them. They are asking me these questions every day, and I must enforce my personality on that party before I can get his confidence. For the benefit of our pursuit, and for bee-keepers generally, I think we must avoid the error of speaking in misleading terms, and thus leading to misconceptions of our pursuit. [Applause.]

Mr. White—When we talk about sugar-syrup let us talk about it as only feeding to winter our bees; that we never sell any of it; it is simply to live on; it is just as good, I believe, when it is "inverted," as you call it—I don't want to know the term, anyhow—but it is just as good to winter our bees. I believe we can winter the bees on it all right, but let it go out that it is for *feed* and *not* for family use.

Pres. Root—If you feed the syrup too thick it will candy and go back to sugar. If you make it thin enough the bees will invert it.

Dr. Mason—Don't use the word "honey" in that connection.

A Member—I always heat the syrup hot. I think that is one reason why it does not candy in the comb.

Mr. York—I want to emphasize what has been said about feeding sugar, and saying what it is used for when you feed it to bees. I am very careful what is said on this subject in the American Bee Journal. I help my correspondents to say what it is used for—to *feed*, and not to produce honey, but to keep the bees alive. I put it in that way.

Dr. Mason—This is really a serious matter; if it should go out to the public that our honored president has been advocating anything of that kind, it would be a great damage to our fraternity here. I say we ought to keep this inside—not to say it at all in the first place. I am in dead earnest about this. Mr. Moore knows what it means. If our president goes out on the market and peddles it from house to house he will find out he would better not say sugar-syrup any more.

Pres. Root—I concede the point Dr. Mason makes, and the point of Mr. Moore and Mr. Abbott, and all these others. I am willing to be corrected on that. I will, if you prefer, use the word "inverted."

Mr. York—we should always say that we feed the bees for winter stores, or to keep them from starving. If the general public only did know, it wouldn't do any harm. But it is hard to get them to comprehend the matter correctly.

Mrs. Dunne—I think in speaking of storing sugar for winter use, we should confine ourselves to the bare fact,

and say it is given to stimulate the bees for brood-rearing, to store for winter food, and give none of them to understand it is to be converted into honey for any purpose.

Mr. Abbott I was writing a resolution, and I don't know as I just understood what was said, but I infer that you meant to say unless the bees invert it or ripen it, it would go back into sugar; that syrup couldn't be made to do it—wouldn't go back into sugar without the bees did something to it. I feed my bees sugar-syrup to winter them; they eat sugar-syrup, and live on sugar-syrup instead of honey; it is sugar-syrup when I feed, and when a bee eats it it is never anything else but sugar-syrup, and I don't see any reason for calling it anything else.

Pres. Root—It is not chemically the same as it was before.

Mr. Abbott—It is absolutely the same as it was before, chemically; I can demonstrate clearly that it is so.

Pres. Root—I am only stating it as have Cowan, and Cheshire, and Dr. Headdon of the Colorado Experiment Station, and other scientists—they called it "inverted."

A. F. Morley—I have been reading that when bees are fed sugar-syrup they will fly out into the air and manufacture it over to some extent before they store it.

Mr. Fixter If you allow the bees to store 25 or 30 pounds of syrup in the brood-chamber, aren't they going to carry that into the sections in the spring? How are you going to separate the sugar-syrup from the honey?

Pres. Root—Not very liable to after that length of time.

SUPERSEDING QUEENS.

Why should a colony refuse to kill the old queen when she has stopped laying, and a young queen has emerged, the colony finally swarming with the old queen that was clipped, there being no eggs or uncapped brood, and but little capped brood in the cells?

Mr. Aikin—For my part, I think there is a mistake somewhere; such things do not occur except as a freak, in all my experience.

Mr. Green—They occur pretty frequently.

Dr. Mason You must be in a freak country; localities differ.

Will a colony superseding a queen swarm with the old queen after the young one is hatched and in the hive?

Mr. Aikin—It is possible that the presence of two queens in the hive, the old and the young, might cause a disturbance; but where the colony would come out I should most certainly expect them to come with the young queen rather than with the old one.

REARING QUEENS.

How often would you put queen-cells in the same hive?

Mr. Aikin—I suppose this is intended for queen-breeders; I can't answer it.

Mr. Hutchinson—I put in queen-cells as often as I take out a queen.

Mr. Holdren That isn't the idea; I want to know, when you are rearing queens, how often you would put cells in the same hive to rear queens for sale?

Mr. Aikin Isn't your thought this: How many cells would you cause one colony to rear?

Mr. Holdren—Yes, sir; without giving them a rest.

Mr. Hutchinson—Perhaps two or three—somewhere in that neighborhood. They will rear one batch of cells in ten days.

NUMBER OF COMB SPACES WITH BEES FOR WINTER.

Taking the Langstroth frame for a standard, how many spaces between combs should be occupied by the bees for good wintering on examination Oct. 15th?

Mr. Aikin I don't know the number of spaces; that will depend upon the temperature, largely, and it varies so much the first of October that probably six or eight spaces would be right.

Mr. Benton Five in sharp weather.

Mr. Abbott I believe that would be pretty close.

Dr. Mason Six makes a good, solid colony.

FORMING LATE NUCLEI.

How late can a nucleus be formed in northern Illinois, using a virgin queen, and build up strong enough to last until spring?

Mr. Aikin That is out of my territory. I should say it depended largely upon the weather and the honey-flow; principally those two things—and the man who is handling them.

(Continued next week.)

Contributed Articles.

No. 2. Extracted Honey Production.

Size of Hives—Plenty of Stores and How They Become Effective—Larger Hives Needed Than in Comb Honey Production, Etc.

BY R. C. AIKIN.

Some months ago I was writing a series of articles for this journal. I concluded the series so far as comb honey production was concerned, and in the issue of June 21, 1900, page 387, I gave the first article on extracted honey production. Just about that time I found myself so occupied with other work I could not continue the articles, hence this lapse or break in the series. In order to get the connection and refresh our memories, I shall have to sum up or repeat a little of the ideas in the former articles.

In the comb-honey articles I taught the great importance of having very strong colonies while section honey was being stored. When entering on the description of extracted honey production, I still advocated strong colonies. I also pointed out that comb honey stock would pack brood-combs very closely with honey, but when extracted was produced, especially with abundance of store-comb, the brood-combs were left very lank or thin. I urged that the apiarist note this difference in the amount of stores found in the brood-chambers, that run for extracted, having brood-combs so very scantily stored as to cause death of colonies from starvation when comb-honey colonies in like hives had stores in plenty.

There is also another cause for starvation of extracted stock, the very fact that the latter stores the honey in the extra, leaving plenty of brood-room, leads to the development of much more brood. The two colonies may not seem very different in strength during the flow, but since the comb-honey colony has its combs with much honey and little brood, while the extracted honey colony has just the reverse, this causes the latter to have a great force of bees after the flow is over. This host of bees produces quite a different condition of affairs from the other.

The great amount of brood and bees with the extracted-honey stock after the flow, may, under certain conditions, be a benefit. Should there be a later flow that these bees can forage upon, they may prove to be just what we want; but if there is a dearth of nectar, and they are in enforced idleness, they may be of little use. If we know perfectly our field we will know just what to do, but it is not always possible to know. However, most apiarists know fairly well whether they are to have any nectar yielding late to employ the bees, and if there is none then it follows that there should be provision made for the conditions. I am using for extracting, 9-frame American hives. This frame being about 12 inches deep, it would be inclined to catch more honey than a shallow frame, yet I find these hives run for extracted honey to contain less honey at the end of the flow than do Langstroth frame hives of the same capacity when run for comb.

I have no late flow, hence the condition on the hive as to stores at the close of the summer flow is the condition practically for winter. As it takes 30 to 40 pounds of honey to carry a colony thru in this field, I am compelled to do more spring feeding of the extracted-honey stock, or else use a larger hive for them. I have before given my experience in this matter, but it will do no harm to state it again. For several years I lost heavily of my extracted-honey stock from starvation and general poor condition in spring, caused by shortage of stores. Since then I have given larger brood-chambers, and, when so, this stock winters and springs as well as comb-honey stock, if not better.

Note that the comb-honey stock well provisioned the brood-chambers, this very fact reducing the amount of bees going into winter. We might reason as many have done in the past, that we do not want a big force of bees to go into winter, that it takes so much to feed them. That argument is very good if the bees are cellared, but for outdoor wintering I believe the big colony the better. It does consume more honey, but then they winter more safely. I have wintered a great many colonies in two-story American hives

right along with one-story ones, and the two-story hives have raising big colonies when the June flow comes, plenty of honey and far more bees than the one-story ones. The big two-story colonies will be storing surplus when the others are barely ready to enter supers. This testimony will give comfort to the Dadants, and I am sure that for outdoor wintering they are right, that the big hive is the better. I believe the net results to be better from such.

In producing comb honey it is true that a very large brood-chamber colony may get to swarming before they do section-work, but this does not apply so much to extracted-honey stock where a set or two of combs above, ready to store in, attracts the bees to them.

Conditions (that is "locality," sometimes) make a great difference. I call the reader to note carefully what I am just now to put before you, for these matters must be understood or you will say the doctors do not agree.

I have been for several years in a field in which the few weeks just preceding the June flow, were weeks of an ABSOLUTE dearth of nectar. Now, reader, suppose you were here with your bees under such conditions. Suppose they were in 8-frame hives, and the last half of May and first half of June there was practically *nothing* for them in the fields, and the stores at home very low. Do you think you would have any swarming? Or even a proper amount of breeding? You would not need to bother your head about how to keep down swarming—I will guarantee no swarming-fever under such conditions.

Now, suppose your bees, instead of being in 8-frame hives, single story, were in two-story or 10-frame ones, stores to be in proportion. I can tell you that such two-story hives well-provisioned, weather warm, and other conditions favorable, you would have *some* swarming before the flow, and much more after it began. You could, by a careful and judicious management, handle your one-story hives so as to have good colonies, but it would have to be done by close watch, and never at any time allow the colony to get out of stores, and while they would have very little ahead make them *handle what little they do have*. One principal factor in inducing free laying by the queen, is to have *workers with full sacs* much of the time.

Thus it is *possible* to have bees carried thru the spring in a dearth of nectar, bringing them up to a honey-flow in good condition and no swarming-fever. Such colonies will go into the sections and work for some time without swarming, many going thru a flow and not swarm if care is used to give and keep plenty of room in supers. But, should there be a little nectar from the fields for two or three weeks *just before* the flow, and at no time a scarcity of old stores, some would no doubt be ready to swarm at or about the beginning of the flow, if not sooner.

Your two-story hives having a great abundance of two things (yes, three)—stores, empty comb and house-room—will breed just about as rapidly under the complete-let-alone plan as will the other with the coaxing and encouragement. The large hive is the easiest to winter and spring, for two reasons: 1st, because they go into winter with a host of bees, and can endure the cold, and so have more bees in in spring to start and care for brood; and 2d, because there is a plenty of feed at all times, both winter and spring. As before stated, I find my two-story hives build up faster in the spring, and make great rousing colonies by the time the others are in fair condition. I can not account for it in any other way than the great amount of brood and bees in the fall being a protection against cold; earlier and more rapid spring breeding from some cause; and a courage and ambition because of the much empty comb to occupy, and back by a rich store of honey.

I wish here to say that there is another probable reason—perhaps I should leave out the "probable." When a colony is wintered in two chambers, that have been under conditions that find the brood and cluster low down or in the bottom hive in late fall and early winter, they work upward in winter and start breeding in the top hive in the spring. This leaves honey below the cluster in lower outer combs, and this they will from day to day carry up and store *above* and *about* the brood. You see, here is a condition that causes the workers to handle honey, have full sacs, also open stores and a well-fed queen and brood. It all conduces to the welfare and prosperity of the colony. It is a condition that is very like a flow of nectar, and is obtained with the least care and labor on the part of the apiarist.

Now I think I hear E. R. Root hurrahing for two-story 8-frame hives, and I think he is not far amiss as to the results to be obtained when they are rightly managed. If you winter bees outdoors, use a larger hive for the cellar,

If you produce extracted, use larger hives than for comb honey. If you use 8-frame hives, use two of them for a brood-chamber in very many cases; but you can contract if you choose, when the flow comes on.

Larimer Co., Colo.

Flat-Bottomed Foundation Securing Drones in the Fall.

BY G. M. DOOLITTLE.

A CORRESPONDENT writes thus: "I have always used foundation having a natural septum or base, but I am thinking of using the flat-bottomed next season. Will you please tell thru the columns of the American Bee Journal whether the bees change the base of such foundation before drawing it out? Or, after drawing it out, will they fill out the corners with wax, or let it remain with a flat base?"

Bees never leave the base of the cells as they come from the foundation-mill making foundation with flat-bottomed cells. This is one reason why there is never a base of yellow wax apparent with flat-bottomed foundation, where such is used in producing comb honey. With foundation having the natural-shaped base, the bees often, in times of an excessive honey-flow, add their own wax right on to the raised part of the foundation, so that this added part can be scraped off with the honey, the foundation washt, and the same be nearly or quite as perfect as when given to the bees. This gave rise to the "fish-bone center" in comb honey, complained of when comb foundation was first used in sections, and the flat-bottomed process of making foundation was invented especially to overcome this "fish-bone," if I am correctly informed.

When bees are given the flat-bottomed foundation, the first thing they do is to go to work to change the base, and in doing this the side-walls are manipulated also, but just how this work is accomplished I have never been able to tell, after all the close watching I have been enabled to do, for when the work is being done, the bee has its head in the cell, hence the vision of the would-be investigator is cut off, so long as the bee is at work.

While I prefer the flat-bottomed foundation to all other makes for section honey, it has two drawbacks, as I look at it, which are that this manipulation of the base of the cells takes time, so that sections filled with such foundation are not completed quite as quickly as is the case where the natural-shaped base is used; and where the sections are placed on the hive before the honey-flow is fully on, the bees will mischievously work at it far more than they will that with the natural base, often gnawing and tearing it all down, where the honey-flow we expected does not come, so that it is necessary to look after the sections to see that they are all right when the bees are about to enter them to fill with honey, after a period of scarcity, or before putting them on for the next season.

I have had scores and hundreds of sections which were filled with this foundation, and which had been on the hives during a period of scarcity of honey, the foundation of which was eaten or gnawed away so that only a neck of foundation, of from a quarter to a half an inch wide, remained next to the tops of the sections, while the lower half of the foundation was very nearly as it was when first put in. When honey commenced to come in from the fields, and the bees began to work on the foundation, it would twist about so that it would touch the separators, and be fastened there. And at the end of the season, when I expected to take off nice comb honey, the whole thing would be spoiled by the cutting and tearing necessary in taking it from the separators. This is the worst trouble I have with the flat-bottomed, and were it not for this, I would not think of using any other make in the sections. Of course, in good years, this does not apply, but in years like the past has been, when fully ten percent of the sections have the foundation badly gnawed in them, it is quite an item.

For brood-frames, I can not see where the flat-bottomed has any advantage over that having the natural base, while it has the disadvantage of taking the bees longer to manipulate it; consequently I prefer the foundation having the natural base for the brood-frames.

GETTING DRONES FOR FALL, WINTER-REARING.

Another correspondent writes thus: "I wish to rear a few queens nearly every fall, but when I wish to do so, I find that the most or all of the drones have been killed off. Can I coax the queen to lay in drone-comb, if the same is

placed in the middle of the brood-nest of a strong colony during the fall months?"

The above is something which has puzzled many a queen-breeder, and while some say they can secure drone-eggs whenever they desire, the trying to rear drones after August 25th, by myself, in this locality, in an average season, has resulted in an entire failure.

The only sure way that I know of, after trying nearly every experiment given, to have drones during September and October, is to mass what drone-brood (the drones from which are to our liking), can be found at the end of our summer honey-flow, placing the same in a large hive which will accommodate all that we may have, making the colony contained in this hive queenless, so they will keep these drones as long as you wish them, which they will do, provided no queen is allowed to hatch in the hive.

If you do not have a hive as large as you wish, you can make one of any proportions you may desire, by tiering one or more on top of each other. Worker brood must be given every ten days or two weeks, in order to keep up the strength of the colony, else they may be liable to be robbed when an entire scarcity comes in the fall. This hive must also contain a large amount of honey, as a hive having many drones in it grows light as to honey quite rapidly, and, if not properly fed, drones do not fly as freely as they should. As our basswood keeps in bloom until August, the drones which are in the egg form, when the combs are mast, will not wear out because of old age before it will be too late to rear queens, say from the first to the tenth of October. In some cases I have had such drones live over, so as to fly quite plentifully on warm days in March and April, though they are soon gone after the bees begin to have general flights.

After all other drones are killed off, if we wish to secure the very best results, this hive of drones can be gone over some day when it is cloudy, and the mercury stands at from 55 to 60 degrees (at which temperature the drones are not likely to stampede off the combs), and all of the undersized and inferior drones culled out and killed, after which we can be almost sure that our queens will mate with the desired drones. This hand-picking of drones is quite a tedious job, but pays well where we have the object of the improvement of stock in view.

I have practiced the above plan for the past ten or twelve years, so I am not entirely ignorant in the matter, and am quite sure I have made much advancement as regards the quality of my bees by so doing.

Onondaga Co., N. Y.

No. 10.—Interesting Notes on European Travel.

BY C. P. DADANT.

THE International congress of bee-keepers took place Sept. 10, 11 and 12, 1900, on the Exposition grounds. Each of the delegates was provided, by the secretary, with a pass, for the duration of this congress, so they could go back and forth without having to pay any entrance to the grounds. I was privileged in the matter of passes, or "service cards" as they called them, for I had been appointed delegate from Illinois to the Exposition, and about all the advantage I derived from it was the grant of two service cards, one for myself and one for my daughter, by the management of the American exhibition. The fee for entrance to the grounds was very low. It had originally been put at one franc (20 cents), but the issue of shares of stock had been accompanied by an equal issue of tickets, so that each purchaser of stock had the value of his stock in tickets. In this manner, 65 million tickets had been issued, and as there were only 50 odd million of these used, the holders soon perceived that the price would have to fall. But it fell below reasonable prices. When we arrived in Europe, the tickets were selling on the street at 7 cents, and when we came back to Paris, in August, they were at 6 cents (30 centimes).

Altho this International congress of bee-keepers was very interesting, I think more beneficial results have been achieved in many of our national meetings; but the most interesting feature to me was the opportunity of becoming acquainted with so many foreign apiarists. If I am not mistaken, there were 15 different nations, 24 foreign associations, and 35 French associations, represented. There were bee-keepers present from South America, Spain, Italy, Russia, Bosnia, Austria, Germany, Belgium, Switzerland, England, and other countries. All but two or three of these men understood the French language, and all the dis-

cussions were in French; but the handling of different topics was placed in the hands of committees with foreign chairmen appointed to control the discussions of these topics, and it was quite interesting to notice the different accents of these men who occupied the chair in turn, and who, altho very familiar with French, still showed in their speech and enunciation that it was a tongue foreign to them.

Having long known the energetic and amiable secretary of the congress, Mr. Caillaud, by reputation, I had paid him a visit a few days previously, at his home, to get personally acquainted with him and also to hand him my credentials, written with a great eulogy, by Pres. Root of our National Association. He received me with the greatest cordiality, and when I offered to pay the membership fee, he stopt me and said that all foreign delegates were admitted as honorary members, free.

So much for French hospitality.

When I arrived at the congress hall, I was stopt at the door by a registering clerk, who askt my name and credentials, before permitting me to enter. I felt rather inclined then to criticise the French love for rules and regulations, which is so conspicuous, not only in France, but thruout Europe. But they took the pains to explain to me that this registering at the door, which seemed to me rather vexatious, was the only method that could be used of compelling members to help sustain the institution by paying their membership fee. Otherwise, they said, a number of people, who can enjoy our meetings, would come and listen and even discuss and vote, and would go home without having subscribed as much as a single cent towards defraying the expenses incurred. I could not help thinking that this was good logic, and that I had heard some of our leading bee-keepers in the United States deplore the fact that there were bee-keepers at each convention who took advantage of the meetings without helping their success in a pecuniary way. If we wish to be hospitable and entertain visiting foreigners without expense to them, we must expect our local men to help us, and a bee-keeper who thinks enough of a congress of this kind to travel a number of miles purposely to attend it, ought to be willing to help defray the costs.

The number of delegates present must have been 150 or more. I have not yet received the report of the secretary, so have none of the proceedings to refer to, and can only speak of what I recall to memory. I was particularly struck by the number of doctors, teachers, and clergymen, whom I met. It seems to me that they must have composed fully a third of the attendance. The peculiar clothing of the French clergy make them so much more conspicuous than our Protestant ministers. But a pleasanter set of men I never met.

Among the subjects toucht in the discussions, I will mention the "Role of the drones in the hive." It seemed to be the opinion of the majority that the destruction of drone-comb and replacing of these by worker-combs, in inferior combs, was desirable, for a motion to recommend this was past, but there was considerable opposition. One member came with a report showing that he had experimented on two hives, the one with many drones, the other with few. I will quote a part of his report:

"In a hive I obtained many drones by placing in it, in the spring, some drone-combs already built and some unbuilt frames with guide, in which, as you all know, the bees would build more drone than worker combs. In another hive I placed combs, built of worker-cells, so as to have but few drones. The definitive gain of the hive with many drones, in weight, during the season, was about a pound. On the other hand, I weighed five hives with many drones, and five hives with few drones. The five hives with many drones increased 116 kilograms. The five hives with few drones increased 123 kilograms."

This shows a difference of seven kilograms, or 16½ pounds, in favor of the hives with few or no drones. But this gentleman does not think that this difference is sufficient to condemn the drones, and thinks they are advantageous in keeping the brood warm. He did not stop to note that before these drones could keep the other brood warm, they had to be kept warm themselves while in brood, and that, too, at a time when the bees are not numerous and the weather is cooler than during the honey crop; and that if there had been workers reared instead of drones, they would be just as likely to be able to keep the brood warm if the weather became cold enough to necessitate this.

But one thing I heard asserted by a number, and which I entirely disbelieve, is that the bees change worker-comb to drone-comb when all the drone-comb has been removed. I do not mean to contradict any one, but I believe that the asserted change from worker to drone comb was not the

work of the bees, but a sagging of the cells in combs of foundation caused by heat. I have seen this in a few instances. But in order to convince me that the bees actually tore down worker-comb to rebuild drone-comb in its place, it would be necessary that the test be made with old worker-comb, in which there could be no prospect of sagging.

But I am running away from my task as narrator and falling into arguments.

Another subject discust, which seems to be of great interest the world over, was that of foul-brood, and it appeared to me that, in Europe as well as in America, many so-called cases of foul-brood are only accidental cases of chilled brood. I say this because I was told by a French bee-keeper that he had had foul brood among his bees, but it had disappeared without his having to do anything for it. And two or three bee-keepers got up in the meeting and asserted that foul-brood was not so dangerous a disease as it had been reported to be, and one man ridiculed all the writers who advise such strong measures against it, but the interruptions and laughing of the majority showed him that he had no hope of convincing them. Several leading men, on the other hand, advised fire and boiling water as the only sure remedies for the true foul-brood, which is evidently a scourge the world over.

Another subject, which has perhaps more importance for the European than it has for us, was the creating of apian classes in schools and colleges. I say that it has more importance over there, because so great a proportion of the population does not seek information, as our farmers do here, thru the daily papers and agricultural press. But it has importance for us, nevertheless, for it would be useful to have, not only our bee-keepers, but all classes, informed, superficially at least, upon the natural history of the honey-bee, its role in nature, and the need of its cultivation.

I had an occasion of ascertaining the total ignorance of some of our average American citizens on this subject, during our return trip to America, on shipboard. To pass away idle hours, the passengers got up an evening entertainment at which each one was required to say, or sing, something for the entertainment of the others, under penalty of the payment of \$1.00 into the sailors' orphans' fund, and they had me down on the program for a talk on bees. I did the best I could, and the few words that I spoke led to more questions than I could have answered in a week, and some of these questions were decidedly foolish.

Mr. Editor, I hope you will excuse me, but it seems I can not avoid tumbling out of my subject. I was quietly taking notes among bee-keepers, at Paris, and here I am, on the ocean, sailing home before time.

This question of teaching bee-culture is fast being solved everywhere. When I visited the old city of my birth

and I may tell you something about this by and by. I entered the doors of the old college in company with the treasurer of the college, who was also entrusted with a school of apiculture in this institution, and on his desk I found a French copy of "The Hive and Honey-Bee." It seems that everywhere they are trying to push the education of the peasants on all agricultural subjects. This is sure to bring results sooner or later.

A Summer of Bee-Keeping in Nevada—Alfalfa.

BY J. T. HAMMERSMARK.

It was on a dark, dismal evening in June that I stepped off a train in the cozy little city of Reno, situated in the mountains a few miles east of the border-line of California. Altho we are in mountains, so to speak, still we are in a valley 10 by 15 miles entirely surrounded by mountains. This and some of the neighboring valleys are very fertile, where water is to be had, but where it is lacking sage-brush and jack rabbits hold the fort. Some few scattering scrub pine trees are to be seen on the mountains. This is all that is left of what used to be a great forest some years ago. The valley is well populated with thrifty and well-to-do ranchers, cattle and sheep men, and bee-keepers. It is about the latter class and their industry that I will give a short sketch.

The bee-keeper's calendar here is just the same as in the Eastern States. We begin our work about the 1st of April and finish up about Oct. 1st, or as soon thereafter as possible. We are not troubled here with the wintering problem, as bees winter well on the summer stands. A great deal of alfalfa is grown here. Two crops of hay are cut each season from this source and the third crop is sold for fall pasture to men who turn their herds and flocks on these fields, which are in a few days grazed to the ground. Our source of honey is alfalfa. It is a very prolific yielder when the conditions are just right. It is something like white clover and basswood in regard to the amount of nectar it secretes; some years it yields more nectar than others, still it is not so subject to short and uncertain crops as the above-mentioned, and many other nectar-yielding plants of the East. One is always sure of a crop altho it may not be more than 40 to 50 pounds per colony some seasons. The average yield for 20 years, I feel safe to say, would not be less than 100 pounds per colony of comb honey. This is judging from past records.

The past season Mr. Hash's crop was 30,000 pounds of comb and extracted honey, being the smallest yield per colony he has had in 20 years, and this was an average of 50 pounds per colony. Some people have asked me since my return to Chicago, if their alfalfa honey is of good flavor.

To this query I can say, yes. The alfalfa honey of this region is preferred to that of California by buyers. In my estimation it comes next to pure white clover honey, if I have any preference at all.

But we have our troubles here, even if we get lots of the best honey produced. Think of a ride on the cars from Chicago, for instance, from three to four days, first thru our fertile neighboring States, then over the vast desert of waste land and mountains of the far West. However, this would not be so bad if the railroad company did not charge you a small fortune to get there. Then, our freight charges are something awful. Suppose I order a carload of bee-hives from the East to be laid down in Reno, Nev. My goods go no further than Reno, but the company charges me with freight to San Francisco, and back freight again to Reno. Of course, they are the big fish and I am of the little fish, and during the present state of political corruption, and as long as the men who make out

In Apiary in Washoe County, Nevada.

laws can be bought and bribed to do as the big fish dictate, regardless of the rights of the people, the little fish must either submit to their robbery and be swallowed alive, or keep out of their way. There are hopes, however, that such things will some day be modified, for the people will not always be silent. Pardon me for switching off on politics, for I intended to write about bees, but you see it naturally came into the subject of our drawbacks in the West, and as this is my view of the matter, if I should not speak of it for fear of offending some one I would not be doing right.

Then, to be isolated in a new country, away from all one's friends, is another thing you have to contend with if you care for society, but if you could make friends in the East you can do so in the West. The climate of this high altitude is simply fine. Reno is 4479 feet above sea-level. Snow can be seen on the tops of the highest mountains nearly all the year round. Bee-keepers at Reno are now suffering from the fact that the place is overstocked with bees, for there are many fine locations in the West, especially if a man has two or three thousand dollars to buy out a well-started place—a man with \$400 or \$500 could get a good start, but of course he would have to depend on other in-

J. T. Hammersmark and Son.

come aside from his bees for a few years until his stock increased to from 300 to 500 colonies, at which time he could depend on making a good living, and most likely accumulate a nice little bank account from the product of his bees besides.

There is another thing I have not mentioned: Alfalfa, I am sorry to say, is cut in its best bloom for honey. I noticed that the bees did not, the past season at least, work more than 7 or 8 days on each crop before it was cut. It is of the sweet clover order. It commences to bloom about July 1st, and will bloom for 10 weeks or more if not cut. What a lot of sweet could be produced from 1,000 acres of Alfalfa raised for seed!

Taking it carefully into consideration, it is a question whether to stay where I am or "go west."

I have given a fair view of both sides of the question, so no one will be misled, I hope, thru the reading of this article. Cook Co., Ill.

P. S.—Referring to the picture of the apiary, I may say that one afternoon a traveling photographer came by our place, and those seen in the photograph came out and looked towards the camera while the man pressed the button. Mr. Hash at the time was away; I am sorry he was not at home, for with his presence the picture would have been complete. The sun was just going down over the Sunset mountains, which we stood facing; that's why we are all squinting so admirably.

The young lady with the white waist is Mr. Hash's niece, who helps him at times during the honey season. The lady at the left in the picture is Mrs. Guthrie, who

came out to cook for us for a few weeks. Her daughter and son are the ones at the right, and the young man in the picture is—myself. Miss Guthrie has helped Mr. Hash in the bee-business for the past three seasons. She is a splendid "hand" and can scrape sections like a machine—so fast and clean. J. T. H.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Moving Bees on the Cars.

I have been thinking of moving to Colorado. Could I take bees that distance—900 miles? If so, how should I pack them to move on the train? Can I make the change, say the latter part of February? NEBRASKA.

ANSWER.—In moving bees on the cars the two things to fear are the breaking of the combs and the smothering of the bees. There ought to be little danger as to the last in the month of February. See that each colony has for ventilation at the entrance or elsewhere a space covered with wire-cloth equivalent to 10 or 12 inches. If the frames are next-distance frames they are all right, but if they are loose-hanging frames, fasten them in place either by driving a nail partially into the end of each top-bar, or by putting in little sticks between the frames. Fasten the hives in the cars so they can not move about, and let the frames run parallel with the rails of the railroad. The excitement of the journey will be a little hard on the bees in February, and will make them eat more than they otherwise would, so they will need a flight sooner than if they had been left in quiet.

Transferring and Dividing Bees.

Suppose we have a colony of hybrid bees in a hive not standard, but full of comb and brood. We can transfer those old combs, but will have to tie or wire them in our new frames. Now, we have eight new hives with comb foundation; and we have coming in the spring—say the first of May—one strong colony of pure Italian bees without a hive, one queen in April, and two more in May and June. We want to increase all we can, and have no weak colonies in the fall. If we had our colony in an improved hive next spring, full of bees, comb, and brood, we would know how to proceed, but if we transfer them we can't expect much increase.

Don't you think it would do to transfer the bees (as they are hybrids) into a new hive, then put the queen that is coming in April into the old hive, then put the colony that we are going to send for, in a hive with full sheets of foundation? Then how are we to get drones to breed from next summer? I do not know whether our old queen is a hybrid, or a daughter of a hybrid.

You might infer from the tone of our letter that we are running this bee-business alone, but we are not wishing to mislead you in the least. We have a good papa who helps us, or rather we help him, but the bees belong to us.

TWO WASHINGTON GIRLS.

ANSWER.—You are mistaken in thinking that transferring will make any great difference in the matter of increase. In the present case it is merely transferring from one set of frames to another, and you can have the brood just as compact after transferring as before, in which case the bees will go right on as if there had been no transferring. If I understand you rightly, your plan contemplates dividing your old colony in April and forming a new colony to which you will give the queen received. It is very doubtful that your colony will be strong enough to divide in April to bear any depletion. The first thing is to have it build up good and strong, and if you take anything from it before that time you will lose by it. You can transfer in fruit-bloom without any loss, but unless the colony is very strong don't divide at that time.

As the colony of Italians you are to get will be without hive, it will no doubt be without brood. So it will be a good plan to have the transferring done before you receive the Italian bees, and then you can give the Italians the larger share of the brood in the old colony. That will make at first a mixt lot of workers in the colony with the Italian queen, but that will be no harm. A week later any queen reared from brood taken from the Italian queen will be of the right stock. Having now the two colonies to draw from, you can form new colonies by taking a frame of brood and bees from each when you want to start a new colony.

By keeping the Italian colony strong, you will be sure to have drones therefrom. When you give brood from the old colony to the Italian, see that you take combs that have some drone-comb in them, but if any drone-comb is in them at the time destroy it by shaving off the heads of the sealed brood and sprinkling fine salt on the unsealed.

Transferring Bees.

1. Which would be the best month or time to transfer bees from common, rough redwood boxes to regular hives?
2. Is it not a rare thing for a few bees (I could not see more than 10 bees), at about 4 p.m., and about half a mile from the seashore, to commence building a comb on the edge of a common cypress hedge, (around an apple orchard four years old), the branch being only about two or three feet from the ground? I could see no other bees but the few workers I mentioned. I was looking at them about ten minutes.

3. I would like to know if it is possible to hive the above bees, and also, how and when to do it. Also, suppose they were hived, would you put the hive on the ground in the same place or not?
CALIFORNIA.

ANSWERS.—1. Probably 21 days after casting a swarm. If you prefer it earlier, take the time when the combs are as light as possible and bees working at the same time. In the North this comes at the time of apple-bloom.

2. Decidedly a rare thing for so small a number as 10 bees to be engaged in comb-building anywhere. Are you sure they were not carrying away wax that had been left there by a swarm that had been clustering there? Sometimes it happens that a swarm starts to build comb on a limb, then leaves, and a few stray bees get left.

3. It is doubtful if you could have 10 bees and get them to stay, and would be of any value should you succeed.

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

FRENCH ANTI-PROGRESS BEES AND PLANTS.

I think most of us were interested in reading how, for the French-speaking portion of the world, the anti-progress monster intrench in the columns of the only French bee-journal was bought and conquered by Messrs. Dadant and Bertrand. We are glad Mr. Bertrand has the beautiful home we read of, looking out upon its beautiful scene. Rather in the nature of news that Mt. Blanc is of three different colors at three different times of the day.

Yes, now editor Bertrand calls our attention to it, it is getting apparent that plants (for their own look-out-for-number-one profit) have three ways of securing the attendance of bees—nectar, pollen, and more or less mysterious dainties, very small in bulk, and of which the bee never gets a load to carry home. (This doesn't prove that the bee never carries home any of these minute secretions.) Mr. Bertrand's experiment of marking a bee at work on his "bar-room plant," and watching it for five hours, consecutively, and noting that the little dupe had nothing to show for its work at the end of the time—that experiment deserves a great deal more attention than it has received hitherto. All of us who pay any scientific attention to forage plants need to be on the lookout. I feel pretty sure that poppies, altho they may furnish some of both pollen and nectar, furnish something else also, and that it is this

"something else" that gets the bees so excited. And I wonder a little if the angelica (devil's club) is not another case of the same thing. I had never heard before that the Chapman honey-plant was of this character. It seems Mr. Bertrand had discovered that before the plant had its boom in this country. I fear we shall find that *all plants which never fail* to attract bees are of this bad kidney, and that all plants furnishing large amounts of nectar have occasional times of barrenness when bees ignore them. Don't let any one tell the man who wastes his time hovering around our horrible *Eryngium giganteum* that that model of industry, the bee, does the same thing.

Do we understand that it was an American plant that scored in Mr. Bertrand's garden the record of rapid growth—an inch an hour? Sounds that way. And if any people have been saying that Mr. Dadant writes nice travel letters with the bees left out, they must admit that he has redeemed himself this time. Page 761.

CAGING AND MAILING QUEEN-BEES.

Forty bees in a very big cage, with both cold-weather room and hot-weather rooms—the way Doolittle sends queens to the Boers. If he would only contrive some way to deprive them of one queen all the world (save one nation) would crown him "king of men." Sixty-five degrees of temperature for your caged queens, whenever you can boss the thermometer. Most of us would have jumped conclusions for a much higher temperature, and Mr. Doolittle deserves thanks for a valuable item. Also those of us who have no experience in caging queens during harvest are glad to be assured that the bees can be depended upon to feed them. Page 742.

NECTAR AND CANE-SUGAR.

It seems to me that Editor Cowan, on page 758, makes a little slip where he says that the sweet of nectar is "almost entirely" cane-sugar. Unless my memory is greatly astray we had, not many years ago, the exact determination of the different kinds of sugars in several samples of nectar made by scientific hands—samples gathered artificially. One or more of the samples showed more than half cane-sugar, but most of them less than half—composition varying greatly according to the species of plant the nectar came from.

ACID TO PREVENT GRANULATION.

I should have used ever so much excess of acid if I had been asked to make bee-feed with vinegar to prevent granulation. If there is another brother as green as I let him make a note. Tablespoonful will do for 10 pounds of sugar, if the vinegar is sharp. Page 771.

INTERNECINE WAR ABOUT PURE FOOD.

Mr. Abbott's speech is quite a refreshing change from the formal tone of the ordinary convention paper. And so there's internecine war between friend and friend among the friends of pure-food legislation. Sad. And all because the butter-folks are set in the resolution to subject imitation butter to additional disabilities, beyond being said under its own name—disabilities more or less inquisitorial. Stated in that way, it sounds as if the Brosius folks are altogether right and the others altogether wrong. But no injustice will be done by stating the other side. I suppose the other chaps will say that people are fooled with bogus butter more frequently than in almost any other way—and more to their disgust; that the person who eats butter is oftener than otherwise not the person who buys it; that present methods inform the buyer what he buys, but not the eater what he eats; and that therefore it is right to protect the eater by forbidding the imitation to be colored like the genuine. That sounds reasonable, too—but it murders an honest infant industry (honesty infantile altho the industry is not) seeing that no one will eat as a *relish* a new stuff that looks queer. But the boy that must have absolutely all the candy he calls for, else destroy all the candy designed for the crowd—I fear the most kindly friend of naughty boys would find it hard to say anything mitigatory for him. Page 773—5.

The Chicago Convention Picture is a line one. It is nearly 8x10 inches in size, mounted on heavy card and 10x12 inches. It is, we believe, the largest group of bee-keepers ever taken in one picture. It is sent, postpaid, for 75 cents; or we can send the American Bee Journal one year and the picture—both for \$1.00. It would be a nice picture to frame. We have not counted them, but think there are nearly 200 bee-keepers shown.

SPECIAL NOTICE!

Last winter's cut of basswood is the whitest it has been for many seasons. We are now making sections out of this new stock and therefore are in a position to furnish you with the very finest quality in the market.

tive side of it; but for the want of space I will not try to give my proof. H. C. HERRING.

Lamar Co., Tex., Dec. 16.

Late Storing—Shorten the Sting.

We have not secured much honey in this locality since 1896. My bees stored a few hundred pounds late this fall, so late that they did not like to go up into the supers with it, so filled everything below, and crowded out the queen so that she could not lay, and so I am afraid that some of the colonies will be short of bees in the spring. I have 125 frames of nice honey, and every hive is full.

We are expecting a good honey crop next year, for the land is green and white clover.

I wish those who are interested in lengthening the tongues of bees could be persuaded to try to shorten the "other end" a little bit! Green Co., Ind., Dec. 15. GEO. SAGE.

Bees Did Well.

My bees did well the past season. I increased from 11 colonies to 23, and got 1600 pounds of fine comb honey.

W. P. BRANSON.

Deatur Co., Kans., Dec. 22.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is, indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and address of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us 1000 NEW SUBSCRIBERS to the Bee Journal (with \$3.00). We will club the Novelty Knife and the Bee Journal for one year, both for \$1.00.

two of them, and O'll try to git me old woman ter be ridin the "Cook-Book"—she won't rade the Journal, an says Oim an Old Sager, bee-jote, an she wishes she'd got marrid to some foine young feller, wid since enuff ter go ter bed at night, and not be spinidin toime an munny wid ould books an papers fall av bees, an no humny in the house, nor wood in the shanty.

Oim hopin luck may strike her wid ter Cook-Book upon Christmas mornin.

CYRENE E. MORRIS.

Carroll Co., Iowa, Dec. 14.

A Slim Honey Crop.

The honey crop was very slim here the past season. The weather is fine now, and the bees have been flying for the last 3 or 4 days, and carrying out lots of dead bees. I am afraid there will be great many of them next spring.

The old American Bee Journal is the pillar of truth. Long may it and its editor stand without fear.

D. D. DASHNER.

Dane Co., Wis., Dec. 21.

Poorest Season in 10 Years.

The past season has been the poorest for honey we have had in 10 years. The bees did not make their expenses—some had enough for winter—some had a little—and others nothing. I fed over 400 pounds of sugar syrup in order that they might have the required amount of stores. Clover looks fine now, and the prospects for next season are very good.

Holmes Co., O., Dec. 17. AMOS MILLER.

Good Season for Honey.

The past season was a good one for honey in this locality. The spring was very mild, and gave the bees an opportunity to gather all the honey from the fruit-blossoms. White clover was never so plentiful as the past summer, altho the weather was not as good as it might have been. Alsike and sweet clover yielded plenty of honey. The bees gathered honey from wild aster and sweet clover during October, gathered pollen from dandelions until Oct. 3, and had a good flight on Oct. 20.

I wish you a happy New Year, and success to the American Bee Journal.

CHARLES DUDLOS.

Saginaw Co., Mich., Dec. 20

Honey Crop Slim the Past Season.

The honey crop of 1900 was rather slim in this county. Clover and basswood failed entirely, so that with the exception of some honey-dew that was gathered in May and June, we had a dearth of honey from apple-bloom until buckwheat bloom. Buckwheat yielded fairly well, and I secured enough to

MARKET QUOTATIONS.

CHICAGO, Dec. 21.—The demand has fallen off very much of late, but prices have not declined to any great degree from those prevailing for the past 60 days, but any pressure to sell would cause a decline. Fancy white comb, 1 lb. No. 1, 15c; amber and travel-stained, 13c; No. 2, 14c; dark and buckwheat, 10c 11c. Extracted, white, 7c 8c; amber, 7c 7½c; buckwheat and other dark grades, 6c 6½c. Beeswax, 28c.

R. A. BUNNETT & Co.

KANSAS CITY, Dec. 21.—Honey market firm, demand steady. In which there is very little movement at present. While we do not change quotations, they are nominal at present. We look for better demand at beginning of new year.

Fancy white, 17c 18c; No. 1, 16c 17c; No. 2, 14c 15c; mixt, 13c 14c; buckwheat, 12c 13c. Extracted, white, 8c 8½c; mixt, 7c 7½c.

W. R. CROMWELL PRODUCE CO.,
Successors to C. C. Clemens & Co.

BUFFALO, Dec. 21.—Honey continues to drag at quotations. Holiday business kills everything, almost, but presents. Fancy 1-pound comb, 15c 16c; common, 10c 14c, as to grade. No extracted wanted.

ALBANY, N. Y., Dec. 22.—Honey market quiet with light stock and light demand, especially for extracted, in which there is very little movement at present. While we do not change quotations, they are nominal at present. We look for better demand at beginning of new year.

Fancy white, 17c 18c; No. 1, 16c 17c; No. 2, 14c 15c; mixt, 13c 14c; buckwheat, 12c 13c. Extracted, white, 8c 8½c; mixt, 7c 7½c.

H. R. WRIGHT.

BOSTON, Dec. 22.—Fancy No. 1 white in cartons, 17c; A No. 1, 16c; No. 1, 15c 16c, with a fairly good demand. Absolutely no call for dark home, this year. Extracted, white, 7c 7½c; light amber, 7c 7½c. Beeswax, 27c.

BLAKE, SCOTT & LEE.

CINCINNATI, Dec. 26.—The market for comb honey here is becoming a little bare, although higher prices are not obtainable. Fancy white comb sells for 16c; lower grades do not want to sell at all. Extracted is selling slow, amber for 5½ and higher; fancy white clover brings 8c 8½c. Beeswax, 28c.

C. H. W. WEBER.

NEW YORK, Dec. 22.—Fancy white, 15c 16c; No. 1 white, 14c; No. 2 white, 12c 13c; amber, 12c; buckwheat, 10c 11c. Extracted in fairly good demand at 7c 8c; white, and 7c for amber; off grades and Southern in barrels, at from 6c 7c per gallon, according to quality. Not much demand for extracted buckwheat as yet. Some little selling at 5c 6c. Beeswax firm at 28 cents.

Demand continues good for comb honey; supply fairly good. Extracted in fair demand with enough supply to meet requirements.

BILDETH & SEGELKEN.

DETROIT, Dec. 22.—Fancy white comb, 15c 16c; No. 1, 13c 14c; dark and amber, 10c 12c. Extracted, white, 7c 8c; amber and dark, 6c 7c. Beeswax, 26c 28c.

M. H. HUNT & SON.

SAN FRANCISCO, Dec. 19.—White comb, 13c 14c; amber, 11c 12c; dark, 8c 9c. Extracted, white, 7c 8c; light amber 6c 7c; amber, 5c 6c. Beeswax, 26c 28c.

Stocks of all descriptions are light, and values are being as a rule well maintained at the quoted range. Firmness is naturally most pronounced on light amber and water white honey, the latter being in very scanty supply.

A HONEY MARKET.—Don't think that your crop is too large or too small to interest us. We have bought and sold five carloads already this season, and want more. We pay spot cash. Address, giving quality, quantity and price.

Apiaries—Glen Cove, L.I. I. J. STRINGHAM, 105 Park Place, New York, N. Y.

Please mention Bee Journal when writing.

Four Celluloid Queen-Buttons Free

AS A PREMIUM

For sending us ONE NEW SUBSCRIBER to the American Bee Journal for three months with 30 cents, we will mail you FOUR of these pretty buttons for wearing on the coat-lapel. (You can wear one and give the others to the children.) The queen has a golden tinge.

This offer is made only to our present regular subscribers.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one of the buttons as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate, it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

Prices of Buttons alone, postpaid: One button, 8 cts.; 2 buttons, 6 cts. each; 5 or more, 5 cts. each. (Stamps taken.) Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

AMERICAN BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., JANUARY 10, 1901.

FORTY-FIRST YEAR
No. 2.

WEEKLY

Mr. C. P. Dadant and Daughter Among the Swiss Bee-Keepers.

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & CO.

118 Michigan St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, \$1.50 a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec 1" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

Reformed Spelling.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th 1899 Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try it. Will YOU have one?

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

YELLOW OR WHITE

Sweet Clover Seed

Free as a Premium

For Sending us One New Subscriber for a Year.

There has been so much written about both the white and the yellow variety of sweet clover, that we will simply say here that if one of our present regular subscribers will send us \$1 with a new name for next year (1901), we will send the new subscriber the balance of this year's (1900) numbers free, and mail, postpaid, to the one sending the new name and the dollar, either one pound of yellow sweet clover seed, or two pounds of the white sweet clover. This is a good chance to get a start of both kinds of these honey clovers. Better send two new subscribers (with \$2.00) and get the three pounds of seed. Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO, ILL.

—BEST—

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

ALFALFA
HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough the Alfalfa extracted.

BASSWOOD
HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Either Alfalfa or Basswood Honey:

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are boxt. This is all

ABSOLUTELY PURE BEES' HONEY,

The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:

I've just sampled the honey you sent, and it's prime. Thank you. I feel that I'm something of a heretic, to sell several thousand pounds of honey of my own production and then buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drink, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honeys of more market flavor, according to my taste.

McHenry Co., Ill.

C. C. MILLER.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

* Editorial Comments. *

A Big Fire—Our Office and Stock Flooded.

On New Year's day the office and floor occupied by the American Bee Journal, bee-supply and honey business, was made almost a complete wreck by floods of water coming down from the upper floors where a big fire broke out about two o'clock in the afternoon. There were something like 20 fire-engines throwing water thru and on the top of the building in an endeavor to put out the fire, and of course practically all of that water came down thru our floor.

Fortunately the issue of the Bee Journal for mailing on Wednesday, Jan. 2d, was still in the office of the printer, and thus was saved, as were also the forms from which it was printed. Thru the kindness of one of our former partners we were able to mail the Bee Journal in his office, thus preventing any delay in getting that number off.

We are writing this Thursday evening, Jan. 3d, and are not sure but that this number of the Bee Journal may be delayed. If it is, it will likely be the first time in 20 years, on the publishers' account, that it has failed to be placed in the Chicago post-office on time. Also, it may be that we will be unable to get out more than 8 pages instead of the 16. If so, we feel very certain that bee-keepers will not complain, knowing that in case of a fire no firm can do exactly as they would under other circumstances.

We do not know just yet what our loss will be on printing-office, bee-supplies, and honey, but feel very sure that it will be sufficiently large. Of course, we had everything fairly well insured, but as all know who have had experience with insurance companies, it will be understood that there is no likelihood of getting the full amount of the loss. This misfortune comes at a time when it is not easily borne by the publishers of the American Bee Journal, so that we would like to suggest that all who are owing on their subscriptions please send it, and also a renewal for 1901. While the loss on account of the fire will be a good deal, it of course will not interfere with the continuation of the Bee Journal. However, everything sent in on arrearages, renewals, and new subscriptions, will be gratefully received at this time.

The fire in our building was one of the fiercest that the fire companies of Chicago have had to fight in a long time, and the weather being extremely cold on New Year's day, it was really very remarkable that the building and contents were not totally consumed. The daily papers spoke in high commendation of the excellent work done by the Chicago fire department. To prevent the total destruction of a 7-story building, 100 feet square, when a great fire is raging at its top, is certainly a wonder. The Chicago fire

department did it, and deserve great praise for their bravery and success.

If any of our readers or customers do not receive prompt response to their letters or orders they will now understand the reason for the delay. Just as soon as the insurance companies have adjusted the losses, we expect to get things in shape so as to be running again as usual. This may take a week or two for the bee-supplies and honey business, but we expect to be able to have our printing-office in running shape again by the end of this week.

The total loss occasioned by fire and water, on building and contents, will likely be anywhere from \$50,000 to \$100,000. There were perhaps ten firms in the building, and all suffered more or less loss.

GEORGE W. YORK & CO.

Bulk or Chunk Honey—that is, comb honey filled in tin cans, and the empty space filled up with extracted honey—has been highly recommended by some bee-keepers, especially in the southwest, but according to E. T. Flanagan, in the Bee-Keepers' Review, it is not wise to put up honey in that form. He seems to think it will be better to keep the two kinds separate, either kind alone bringing more than the two mixed. With such diametrically opposite views it is hard to tell just what to believe, unless it be that local preferences may have a bearing. As a bit of experience in the matter, Mr. Flanagan says:

Some years ago, having sold all my own crop of comb honey, I went to St. Louis to get a supply. At one of the largest commission houses in the city, where I frequently dealt, I inquired if they had any comb honey on hand. "Yes, a very fine article: come and take a look at it." I did, and found over 100 cases containing 120 pounds to the case. I supposed the one showing me the honey had made a mistake, for I thought the cases contained extracted honey, but I found the 120-pound cases filled with as fine comb honey as I ever saw, but in 60-pound cans. I asked the price, and was more than surprised to find it only 6 cents a pound, when I had come prepared to pay from 12½ to 14 cents for good section honey. I asked them to remove a portion that I might examine it more closely, but it was impossible to do so without breaking and tearing it all to pieces. Of course, I did not buy a pound of that honey, for I could not use it. I could not sell it to my customers for as much as clear extracted honey. Now, that was a No. 1 comb honey originally, and it would have brought 15 cents per pound at wholesale readily had it been in sections. I was there to give that much for as much of it as I needed, but I would not give the five cents per pound that they subsequently offered it to me for, and I believe they sold it later for 4½ cents per pound. How much the poor fellow netted on that fine lot of "chunk" honey I leave you to figure out. I only know I was sorry for him, and glad I was not in his place.

Building Up Weak Colonies for the honey-flow is not advisable in many cases. If it be done at the expense of colonies only fairly strong in a region where the honey-flow closes rather early in the season, it will be at a loss, and a reversal of the practice would be advisable, that is, drawing from the weak to help the strong. But where the season is sufficiently long possibly in any case where colo-

nies become *very* strong—it is possible that the very strong may be made to help the weak so that the total harvest may be increased. With regard to weak colonies, Wm. McEvoy has struck a new thought, which he gives in the Canadian Bee Journal. He says that larvae in weak colonies are not fed as well as they should be—a thing not so hard to believe by those who are familiar with the fact that larvae are not always fed alike. So he has thought out a plan by which he kills two birds with one stone—he secures the feeding of a part of the larvae in strong colonies that left to themselves would have been fed in the weaklings, and at the same time gets the weak ones strengthened. Here is his plan :

Just as soon as the strongest colonies are in shape to put the extracting-combs on, I lift up a comb full of brood that is about ready to be capt, and place it above the queen-excluder, and leave it there for nine days. I do this with every strong colony.

During the nine days the bees in these strong colonies will feed the larvae extra well, and all that was in the egg form when I placed the combs above the queen-excluder will be capt brood at the close.

At the end of nine days I take all the combs out of the brood-chambers of the weak colonies and fill up every brood-chamber with capt brood from these top stories, and in a few days after this is done the capt brood will be hatcht out, and these weak colonies will be full of bees. The combs that I take out of the brood-chambers of the weak colonies I put in the top stories where I took the capt brood out of, and let them have that in place of the brood I took from them. The bees in the strong colonies feed the larvae given them from the weak colonies well as before.

Locating and Starting an Apiary.—Mr. G. M. Doolittle works up some very interesting and profitable apiarian conversations with himself in each number of Gleanings in Bee-Culture. In the issue of Dec. 1st, it happens to be about locating and starting an apiary. His responses to questions may be summed up something like this :

Unless a prospective bee-keeper has some knowledge of the business, 25 colonies would be too many to start with. He recommends reading one or two of the standard bee-books, and the taking of one or more of the best bee-papers. So much for necessary literature on the subject.

As to placing hives, Mr. Doolittle would have them level from side to side, and slanting just a little toward the front, providing the frames run the usual way of the hive—from front to rear. If the frames run from side to side, then the hive should stand level both ways.

Mr. Doolittle recommends placing the hives three inches from the ground to prevent the bottom-board from warping, and also to give the bees a better chance to get in on cool, windy days in early spring, thus preventing loss of bees at a time when one is of more value than a hundred after the honey harvest.

On the nearness hives should be together, Mr. Doolittle says his apiary is laid out on the hexagonal plan, the hives being ten feet apart in the rows from center to center, and the rows ten feet apart. This is how he would proceed to arrange the hives as suggested, supposing the apiary finally to contain 100 colonies :

"To get the hives arranged in the hexagonal form, get a line 100 feet long, having a pointed stake tied on each end. Five feet from the stake at one end tie to the line a white thread or string, four or five inches long. Five feet from this white thread, tie a red thread or string, and then a white one five feet from the red, and so on until you have red and white threads alternating at five feet from each other the whole length of the line.

"The line is to be stretch where you wish the first row of ten hives to stand, then you are to stick a little stake at every white thread. Now move the line ahead ten feet, when you will stick the little stakes at the red threads. Then move ahead ten feet again, sticking the stakes at the white threads, and so on until you have stuck the 100 stakes

for the stands for your 100 hives or colonies you expect to have in time. Having your stakes all stuck, level off the ground about each stake until you have a nice broad level place ready to set a hive on at a moment's notice at any time. Having it completed, and each stand occupied with a hive of bees, if you are like me you will consider that for convenience and beautiful appearance this plan is superior to any other."

On the facing of the hives, he prefers to have them toward the south, tho some of the best bee-keepers in New York State advise southeast, for then the morning sun will cause the bees to gather earlier in the day. He comes out very strong against facing hives to the north in a cold latitude.

Next—A Machine For Uncapping Honey.

BY "OLD GRIMES."

THERE seems to be some stir in the busy world of bee-keepers, and the ingenious fellows are determined to place obstacles in the path that has been beaten by us old fellows. We must needs use them, stumble over them, or make new paths around them.

Just now the uncapping-machine is racking the brains of these geniuses and Old Grimes wants to have his say about the matter. Off and on for a number of years I have wielded the Bingham knife, and quite successfully, too, and I expect still to wield it for an indefinite period, but if we are to have a new-fangled way of uncapping, the Grimes family wants a practical, up-to-date machine.

The first idea that enters the brain of the uncapper inventor is to shave off both sides of the comb at once; but looking at such a machine from a practical point of view, how much time will be gained? For a slicing machine to work nicely the combs should be quite uniform in thickness and with a smooth surface, but the average bees will make more or less hills and hollows upon the combs, and these defects are more or less according as the season is a good or poor one, or as the honey-flow is slow or rapid. With many combs the machine would have to be set to take off all down to within a quarter of an inch of the septum, and that would never do, for it would be taking away too much of our good combs, and the tank would have to be placed under the uncapping-box instead of under the extractor.

If we try hard to get really nice combs for the machine, they are equally nice for rapid work with the knife. To get nice, fat combs for extracting, the Grimeses use 8 combs in a 10-frame super. It does not take an expert long to uncup nice combs; then we save much uncapping by extracting when the comb is one-half or two-thirds capt—two strokes to a side usually finishes it. From actual timing a comb can be uncapt in from five to fifteen seconds, or an average of five combs per minute.

We must take into consideration the time for adjusting the machine, and the time to change the knives for a water-bath, for no form of knife will run long without getting that gummy edge; then there is bee-bread to clog the machine, and more or less brood in the way. Perforated metal would prevent the latter.

But let us figure a little. A machine would necessarily cost from \$15 to \$20. There are but few of our extensive bee-keepers who use perforated metal. In order to use the \$20 machine a hundred dollars or more will need to be spent for excluders. The large apiarist would be the one having the most interest, and a machine to become a success with him should be a very radical improvement.

In a paper which was read before the California Bee-keepers' Association by "Rambler", and afterward published in this journal, he seems to set the pace for a machine to uncup several combs at once. That is a radical improvement in the right direction, and while we are inclined to say that it can't be done, it is very unsafe to say it, for more wonderful things than that are being done every day in this age of improvements.

I hope inventors will not take the above comments in the nature of a wet blanket. They are intended to lead

them to see the correct method, and not waste time upon a machine that will be but little, if any, better than the present knife. Instead of conforming to present usages they should seek in a field where the improvement would be so valuable as to lead the extensive bee-keeper not only to buy queen-excluders but to revolutionize his entire apiary, hives, etc., if necessary. There will be something of a reward for the inventor who will climb to this mark.

No. 11.—Interesting Notes on European Travel.

BY C. P. DADANT.

DURING one of the sessions of the International congress of bee-keepers, a French bee-keeper, Mr. Giraud, exhibited a frame containing dipt queen-cells, reared by the Doolittle method. This was a new thing for many present, and I wish that Mr. Doolittle had been there to take a little of the praise that was bestowed upon this practical demonstration of the success of his teachings. Mr. Giraud and his three sons are practical, wide-awake apiarists, and have been for several years readers of an American bee-paper, and it was in this that they found the Doolittle method. They stated that they had reared 314 queens during the season of 1900, in the best one of their colonies, while the queen was laying and the bees working in the customary way. They used an 18-frame hive divided in two by a perforated zinc, and on the outside of the zinc they kept two frames with the dipt cells between two frames of brood, and kept adding more queen-cells as they removed the ones that were ready to hatch, and which were given to nuclei made by our method. An account of their doings so interested Mr. Calvert that they gave him two photographs of the artificial cell-breeding, and furnish him with a statement in French that I translated for him.

On the last day of the congress, the secretary of the committee on Apian Statistics made his report on apiculture throughout the world. He had received so voluminous a correspondence from the different countries of Europe, and from America, on this subject, that it was impossible for him to give more than an abridgment of the statistics. But the detailed report will certainly be very interesting, and I hope to be able to give extracts from it to the readers of American Bee Journal whenever the printed report reaches me. I noticed with great pleasure that the report obtained from our own country, sent by the Department of Agriculture at Washington, was quite extensive. He also had reports from some of the States of South America.

During the afternoon session of the last day, the congress decided to hold its next meeting at Bois-Le-Duc, Holland, in 1903, with the same executive committee as for this congress. Messrs. Bonnier, president; Sevalle, vice-president, and Caillaud, secretary.

That same afternoon, as the business of the congress was about over, and the sky was clear, as it had not been since our arrival at Paris, we ascended to the top of the Eiffel Tower—Mr. Calvert, my daughter, and myself. Going up into a monument a thousand feet high is not a thing of very great interest after one has been on mountains eight or nine thousand feet above sea level, but there is certainly no mountain in the world from which one can see as great a gathering of civilized people, as many mountains, or as many houses. The ascent may be made either in an elevator or by a stairway, but we selected the former without hesitation, for just the looks of the spider-web structure of the stairway was enough to make us dizzy, and it costs just as much to walk as it does to ride. The elevators are large enough to contain some 60 persons, and they were full every time. And they are run very smoothly, and start with so slow a motion that one does not at all experience the sensation of falling down into a bottomless pit, as one feels when let down with a jerk from some of Chicago's sky-scrappers.

From the first platform, 200 feet up, one can view all the monuments of Paris, some 50 or sixty of them being very conspicuous because they loom up above the houses. The H shape of the Exposition grounds also shows itself plainly, and in the background, on one side, the heights of Montmartre, and on another the fortress of Mont Valerian stand in full view above the sea of houses. But when one attains the third platform, at a thousand feet of elevation, everything flattens down—the monuments, the hills, the white ribbon of the Seine, the Bois de Boulogne, the dozens of villages, seem only like a living map. A trip in a baloon would probably give a similar impression. The houses

make a sea of red tiles, the river is a silver thread, and the parks are green spots here and there.

Speaking of parks reminds me that I failed to mention my visit to the experimental apiary of the Garden of Luxembourg. It was a disappointment. The spot is unique, for an apiary in the heart of one of the largest cities in the world. It is a very quiet corner, among the trees, the shrubs and the flowers, in the aristocratic garden of the palace of the French senate, and the bees fly back and forth unmolested and busy. But there are only a few hives, in a rather dilapidated condition, and it is evident that no pains are taken with them. The keeper very kindly permitted us to look at everything. We found half a dozen different practical hives, rotting without occupants, while a half-dozen straw-skeps and two or three odd patents seemed the only experimental feature. I inquired for an observation hive, and he showed me a hive with eight or nine frames with glass all around. What one could observe with such a hive is more than I could say. I was told that lessons in bee-culture were given every two weeks, in this place, during the summer. I doubt that any experiments of value are ever made there. France can afford something better.

In the evening of the last day, the apiarists of the congress were gathered at a banquet, in one of the restaurants of the exposition grounds, and numerous toasts were offered to the visiting delegates, who returned the compliments as best they could. On leaving, we opened our purses to pay our share, but the secretary, Mr. Caillaud, informed us that the foreign delegates were guests, and that their expenses, even to the tips for the waiters had been paid by the management.

The following days two excursions were arranged, with special trains for the delegates to visit the apiaries of two of the members, all expenses paid by the association, and I regretted very much that I could not take advantage of this; but my time was limited, and I had to leave Paris that very same day.

If the Europeans are behind us in the matter of convenience of railroad cars, they are certainly ahead of us in securing cheap transportation. If I remember rightly, the amount paid by the association for these two excursions was less than a cent per mile, per person. Perhaps we will also get cheap travel here by-and-by, but in the meantime we need not be afraid of the cost of traveling in Europe, after we are accustomed to travel in this country. But I earnestly hope that we are not going to take the habit of "tipping" the waiters and servants as they do over there. It is sickening. You eat dinner—tip. You ride half a mile and discharge the cabman, pay—and—tip. You go to the theater, buy your ticket, and tip the ushers. You leave the hotel, tip the servants, the boot-black, the chamber-maid, the porter. Tip, tip, tip. Luckily they do not expect silver in every case, and this is the principal use of coppers. Two cents, three cents, make a very passable tip. If you give a dime, you get a smile. If you give a quarter, you get a fine bow. But if you give nothing, you had best not look behind, for a look of contempt will follow you till you are out of sight.

“The Hum of the Bees in the Apple-Tree Bloom” is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a “hummer.” We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription *a full year in advance*, we will mail you a Wood Binder free—if you will mention it.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Convention Proceedings.

Report of the Proceedings of the 31st Annual
Convention of the National Bee-Keepers'
Association, held at Chicago, Ill.,
Aug. 28, 29 and 30, 1900.

BY DR. A. B. MASON, SEC.

(Continued from page 6.)

COMB FOUNDATION—EXPERIMENTS, ETC.

Prof. Gillette—I have been experimenting some the last three or four years at the Colorado Experiment Station, at Fort Collins, to determine the manner in which the bees handle the foundation that is given them. It seems to me on so very important a question we ought to have more light. What weight foundation is best, for example, to use in the brood-chamber, and what is the best weight to use for comb honey? and to what extent does the giving of the foundation lessen the wax secreted by the bees? Do the bees really take the wax from the foundation and build it up both in the cells and down in the midrib of the comb? If so, to what extent? The experiments that I want to report upon are chiefly along these lines, and before proceeding, I might say what I say to you was published just recently in Bulletin 54 of the Experiment Station at Ft. Collins, which any of you can obtain, so long as they last, by simply addressing a letter to the director, and requesting Bulletin 54, on "Experiments in Apiaries." First, I thought I would endeavor to determine definitely whether or not bees do use the wax in the foundation. Everybody believes they do; no one doubts it; but I wanted absolute proof of it. I went to Mr. Elliott, who makes comb foundation, and asked if he could make for me some rather light foundation, and work into it a large amount of lampblack so as to make it exceedingly black. This he did, as you can see by looking at the sample of foundation which I have here—a small piece of it just as black as coal, or nearly so. This is about a medium weight of super foundation for comb honey; that was used in the sections. I used a strip one inch wide at the top for some of the sections, but others I put in a full sheet; by "full sheet," I mean a sheet like that of the black foundation. I find I haven't in my trunk—I didn't come from home and have not the samples that I had from the experiment station to show you, but I will simply have to tell you, and you will have to take my word for it. Where foundation like that was used, about one inch, it was worked down into the comb so that the black color would show nearly to the ends of the cells. I happen to have a little piece here from the full-piece foundation. This was fully drawn at the center; this comes out here near the sides. The cell-walls thus far [indicating] are black, and the foundations used are nearly so.

A Member—Do I understand you to mean the black worked down from the strip of lampblack foundation at that part?

Prof. Gillette—Yes, so that in cutting thru the comb and looking at the edge of it, the black nearly faded out at the ends of the cells.

A Member—What was the object of getting that black to start with?

Prof. Gillette—To see to what extent the bees did take that wax, and whether they used it right there where it was placed, or whether they carried it all over the hive and used it in the foundation; in some places, a small amount of black wax was taken up by the colonies and used in sneaking, but not to any great extent did they carry it away into any other section—used it right there; drawn right down into the midrib of the comb. Having proved definitely that they do use the wax in this way, I wanted to know whether or not they get that wax from the midrib of the foundation, or whether they get it from the cell-walls. For example, let that represent a section, the foundation, as you look at it, are the edges there. In any foundation there would be found, or in nearly all the foundations there would also be a short cell-wall as shown there. Now, do the bees get this wax that they build the cells out of, wholly from those little short cell-walls, or do they go down into the base and midrib itself, and use it in building out the cell-wall and extending the midrib? First, do they use the

wax that is in the midrib? This I determined by three or four different means. First, by weighing the midrib. They drew out this wax into combs. The comb was then put into water and the honey all extracted, if they had filled it with honey. The cells were scraped off from the two sides, until they had only the midrib left. Here, for example, is a midrib that has been built out in a comb and the cells taken off again. Here is a sample of the foundation, on which that comb was built. Then I took pieces of foundation and of the midrib from the comb on that foundation, cut them in different sizes, and weighed them, and I found that the weight of the original foundation was considerably more than the weight of the midrib taken out of the comb built upon that foundation. But now it might be possible that the difference in the weight was all due to their using these little short cell-walls. The very heavy foundation weighed 11 grains to the square inch. Septum from the comb only weighed eight grains to the square inch after the bees had built the comb upon it and the comb-cells had been removed; then there is the difference between 8 and 11, or three grains to the square inch of the septum that had been used. In case of medium foundation, of which I have a sample here, and a sample of the midrib of the comb built upon this foundation—the foundation itself weighed 8.4 grains to the square inch; this midrib out of the comb weighed 5.18 grains to the square inch, being a difference there of about 3½ grains to the square inch of the midrib that the bees had used. The deep-cell foundation was also used; the foundation weighed 5.46 grains to the square inch. After the comb had been built upon the foundation and the comb-cells removed, then the midrib weighed only 3.44 grains to the square inch; but if I should take this foundation and cut off the deep walls here, just as close as I could, this foundation midrib weighed only 2½ grains per square inch. It actually weighs less right here in this foundation than it does after the bees have built the comb upon it, because they do fill in, in some places, on the bottom, and make it a little heavier, and the natural-comb septum, taking comb the bees have built entirely, not having given them any foundation at all, removing the cell-walls and taking the midrib of this comb, and it weighed but 2.1 grains to the square inch. The difference in weights here was evidently more than could be accounted for by the removal simply of these small cell-walls.

A Member—Were all those tested alike, by being immersed in water?

Prof. Gillette—No, sir, not in all cases. There were cases where there was no honey at all. Those were not put in water. In all cases they were thoroughly dried before using; very frequently two or three days elapsed before they were used. The next method which I used for determining whether or not they take the wax out of the midrib, was to fill the comb with plaster, and that was suggested to me by Pres. Root. I filled the comb with plaster at Paris, and making sections of it and measuring the width of the midrib, and cut in that way, as Pres. Root has explained in his paper, this holds the midrib; it is perfect, it is not spread out at all. I found by measuring the midrib of the comb built upon a foundation it was in all cases where heavy foundation was used the comb was very thin. In cases where light foundations were used, foundations in which the midrib does not extend seventeen one-hundredths of a millimeter, that they did not thin the midrib to any extent, usually not at all, which seems to me quite an important matter. If the midrib of the foundation does not extend seventeen one-hundredths of a millimeter in thickness, the bees will thin it but little, if any, very little indeed; very often scratch it over to make it opaque, but very little used; if thicker than that, they are sure to thin it some, but never thinning it down to the thinness of the midrib in the natural comb. Is that clear? If you use a heavy foundation the bees never thin the midrib down to the thinness of the midrib in the natural comb not in any case that I have found. I have placed upon the table here some of the different midribs that have been taken from combs; here is a specimen of midrib from natural comb, all made by the bees, and those other midribs are midribs taken from different specimens of combs made upon foundation. You will not find any as light as the natural-comb midrib, except in the kind where the deep-cell foundation is used. In some of those cases it is as thin as the natural. Do the bees thicken the walls of the comb where it is built upon foundation? I think there has been a difference of opinion in regard to that, some thinking that no matter how thick—how much wax you may put in the little short cells of the foundation, the bees will always thin it down to the thinness of the naturally built comb. To determine that point I proceeded in

this way: I took a goodly number of pieces of comb that had been drawn by the bees, and some natural comb, other samples of comb that had been built upon different kinds of foundation. And care was always taken in this case not to use a comb that had been capt, because, if the comb had been capt, it would have to be uncapt and the honey extracted. In that case, the ends of the comb would have to be removed, so I always took a comb that had not been capt. I found that by taking these samples of comb, scraping the comb-cells all off from the foundation, the wax of the midrib is left, and I consider these weigh the same perhaps in natural comb—that the bees do thicken the surrounding walls of the comb, so that they are heavier, as well as the midrib of the comb, and that is brought out in some figures that I have put upon these sheets of paper. In this chart—I don't know whether you have read it or not—you will note in this column is given the kind of foundation used, the first lot having no foundation at all, being natural comb; the next shows the thickness of the comb used. In this column I have given the weight of the entire comb per square inch. Suppose this was the comb, suppose it is an inch thick; we have given here the weight of a square inch of that comb. In the next two columns I have separated the weight of the comb into two parts—the weight of the midrib of that comb and the weight of the cell-walls in that comb, so as to give the two separate. We will take first the natural comb, which is 1.37 inches thick. You will understand I could not get comb made to order, but had to take samples out of the hive—the thickness as the bees had made it, getting them as nearly alike as I could, and taking the actual measures, comparing those that were nearest alike. In case of natural comb 1.37 inches thick, a little thicker than this comb here [indicating], the weight of that comb alone per square inch was 13 grains; the weight of the midrib averaging—I have given here in every case the average weight gotten by weighing quite a large number of samples, not giving the different weights. In this column I have given the weights of the cell-walls themselves—the wax in the cell-wall. The wax in the cell-wall here weighed 10.8 grains; in the midrib only 2.10 grains. This [indicating] is a sample of deep-cell comb, comb built upon this deep-cell foundation that was put out in 1888. Take the first sample 1.44 inches. This is a little heavier than the 1.37, the first one that I had in my samples to compare it with; the midrib there weighed 13 grains to the square inch; here it weighed 16.63—a difference of 3.63 grains for this comb. It is a little bit thicker, as you will see. The difference in the septum of the midrib is the difference between 2.1 and 3.7; the difference in the weight of the cells would be the difference between 10.8 and 12.93; those are the only two samples that are very close together in comparison with those weighed. We might pass to another sample of this deep-cell; the comb weighed 14.9, almost 15 grains to the square inch; the comb here weighing 13 grains to the square inch.

A Member—You have one there in the natural comb just exactly the same.

Prof. Gillette—That is right. I want to call attention first to the fact that this 1.13 style gives a heavier comb. This is 11.6 grains to the square inch while the other was 10.11 where it was 1.37 in thickness; comparing these with samples of comb of exactly the same thickness 1.13, the whole comb weighed 9.55 grains to the sq. inch; the whole comb here weighed 14.9 or almost 15 grains to the sq. inch; the midrib weighing 3.3; the cells themselves with the midrib removed weighed 11.6 grains, whereas up here they weighed 7.2 grains to the square inch. It is true in all the cases, where these heavy foundations were used that the weight of the cell-walls was increased as well as the weight of the foundation. I want to call attention to one overstatement in my bulletin which Pres. Root has also called attention to. I stated that the increase in weight of the cell-walls was greater than the increase in weight of the midrib where the heavy foundations were used; that is only occasionally true. It is often true that the increase weight of the comb is due more to the added wax in the cells than to added wax in the midrib. The increase weight of the comb is due to the increase wax in the cell-walls as well as the increase wax in the heavier foundation where the heavier foundations are used. That isn't true often where the foundations are, for example, the extra-thin and the thin foundation, and the rather shallow foundation put out by the Root Company. I found with those the cell-walls in the comb were just as light in many cases—in fact quite commonly so—as they were in the natural comb; but it seems to me it is proved beyond any doubt that if we add a large amount of wax, either in the midrib or short cell-walls of

the foundation, we will always increase quite perceptibly the weight of the comb built upon that foundation. There is one other point which I will take time to bring out and that is: To what extent do we economize the secretion of the wax when we give bees comb foundation to build comb upon? To make the question a little clearer, if we give bees foundation that has wax enough in it already to build the whole comb, will they then secrete any wax, or use that wax and build the comb up? To bring that point out, let us refer to the figures that I have already upon the board. I might go on thru the list of these, but I think the examples I have used are enough. I used one foundation, this very heavy foundation which would average 11 grains to the square inch when cut up. Natural comb built by the bees, the average weight I found to be 10 grains to the square inch, the comb being one inch thick in both cases—10 grains to the square inch in the natural built comb, where it was 11 grains to the square inch in this foundation itself. Those are samples of comb one inch thick [indicating.]

Dr. Mason—One inch thick or one inch square?

Prof. Gillette—It is a comb one inch square. The comb built upon these heavy foundations, built out one inch thick, weighed 18½ grains to the square inch. Natural comb, as I told you, averaged only 10 grains to the square inch. The bees then having one grain to the square inch more wax than they needed, added to that foundation 8½ grains more of wax. In other words, you gave your bees 18½ grains of wax to save their secreting 2½ grains of wax, because 2½ grains added to 7½ make the 10 grains the bees would have used if they built this themselves. Take the lighter foundation, the medium Root foundation, running, I think, about 7 sheets to the pound, that foundation averages 8.4 grains to the square inch. The comb built upon it weighed 16½ grains to the square inch; that is, combine one inch thick, the bees added to that foundation so as to make it weigh 6½ grains to the square inch more than that natural comb would have weighed if they had made it all themselves. You give the bees 8.4 to save them from secreting 3.5 grains of wax. Without going thru the figures of the different weights, I found, I might say, that held thru all the tests I made. That is, to all these heavier foundations the bees still added a very large amount of wax from their own secretions, altho they did not need to do it. It seems to me that we only economize the secretions of the wax on the part of the bees to a very small extent by giving them wax in the foundation. It seems to be the nature of the bees when building comb to secrete wax, they go on eating honey, I have no doubt, and secreting the wax to a very large extent, even the wax was given them to begin with. Then what kind of a foundation can we use that would be most economical in comb building? Without using the figures, I might simply say I found the greatest economy apparently from my own measurements to be in the foundation which has, as measured, as nearly the weight of the natural comb midrib as you can get it—the foundation with the midrib just as near the natural as you could get it, and with not a very large amount of wax in the cell-walls of the foundation. I presume you have all used, to some extent, this rather short deep foundation. It seems to me that contains about as much wax in the cell-walls as can be given with the greatest economy in the building of the comb. I believe that is all that I will take time to tell you about now, unless you wish to ask questions, except simply to call your attention to some of the samples that I have here. In these little paper boxes, I have placed samples of sections of comb and of foundations, and many of them are arranged in this way—one of them showing the section of the foundation and the other the section of the comb built upon that foundation. I would like to have you examine the two and compare them, and see if you can see with your naked eye the comb built upon the foundation and midrib thinner than that built upon the foundation. Some samples show plainly, and I have marked it in this way: A sample marked A would be a sample of a foundation cut thru; a sample marked A would be a sample of the comb built upon that foundation. The same is true of B, C, D, and so on. By bearing that in mind, you can tell which is the section of the foundation and which the section of the comb built upon it. I have also one or two sections here of the comb cut at right angles to the cells, and I would like to have you see how very delicate and beautiful the section of the natural comb is in that way. Also on these two pieces of boards, I have a sample of foundation and also a sample of the septum of comb built upon that foundation, and you can make comparisons of them. These can be past around.

D. H. Coggs—I have noticed where we run for extracted honey, in increasing my amount of combs for ex-

tracting purposes, that by slipping a sheet of foundation in with the other combs, the bees will use their surplus wax that they produce on this foundation, and it saves me bur-combs. They don't crowd the extracting place; where there is a surplus place they fill up, they don't crowd so; where there is no foundation in there, they will crowd every spot and fill it all up with bur-combs. To overcome that when I extract, I cut deep slices from the combs; that wax goes in with the cappings, and I have it in wax. That is the way I overcome the bur-combs. Otherwise I claim the wax would be wasted. They will produce wax when they are gathering honey fast, and they must have some place to put it.

Pres. Root—With regard to this matter of foundations, we have Mr. Rankin here of the Michigan Experiment station who wishes to relate some of his experiments, which I think will bear out the experiments already given by Prof. Gillette.

Mr. Rankin—We had some samples of foundation which were made by the A. I. Root Co., of different weights, ranging all the way from 8 to 13 sheets to the pound. The sheets were the size of the Langstroth frame; we used these foundations in different ways thru the hives, and I used different methods of wiring. We used the vertical wires, some with 5 and some with 8 in a frame, and we used the horizontal wires 4 and 8 in the frame. We found it worked the best on the horizontal wires, every time. The vertical wires gave no satisfaction at all. There would be a weight between each wire, and the foundation stretch. With the horizontal wires the wires sagged and the foundation stretch and left a perfectly straight comb. I was showing it to Prof. Gillette when he was at the college. I think he would bear me out in the statement. It seemed a little bit strange to me, and quite interesting, and I might say, too, that the foundation with 13 sheets to the pound seemed to give just as good satisfaction as that of 8 sheets to the pound. I think that the lighter we get our foundation the more economical, and it will answer the purpose just as well. Two years ago we had an experiment in surplus honey. The advantage of full sheets or half starters has been clearly analyzed. It is shown there is just a little over one percent more wax in the sections which had the full sheets of foundation than those which had half-starters. The foundation used was Root's extra-thin, also the Dadant. There is no difference in the two foundations.

Pres. Root—The experiments which have been given, are quite interesting; they show bee-keepers have been using too heavy foundation. There has been too much wax in the midrib certainly, and, probably, too much in the walls. The experiment which Mr. Rankin gives, that 13 sheets to the pound, wires horizontal, give as good results as 8 sheets to the pound, wires horizontal, is quite remarkable. It isn't our experience, as I remember, but it is possibly correct. I think it would be well for bee-keepers to begin using four sheets to the pound. If you are using too much wax, you ought to know it. The experiments shown here, as given by Mr. Rankin, seem to indicate that you can use thin foundation in the brood-frames. We have been working, and so have all the foundation-makers, towards lighter foundation. Several years ago, heavy foundation was used by bee-keepers, and later they have been using lighter foundation, which has been a great economy to the bee-keepers and saved a great deal of wax as well.

Dr. Mason—Mr. Rankin stated in putting in vertical wires they sag; that hasn't been my experience. I use vertical wires and make my foundation right on the wires. I have tried the horizontal wires, and with me it has been a failure every time; a good deal more sag to it than with the vertical wires.

Mr. Fixter—Have any tried foundations milled at different temperatures, and found any difference in the working of the bees upon them? Which do they find best—the wax that is hard and stiff, or the soft, pliable wax?

Prof. Gillette—I have made no test.

Mr. Rankin—I don't know anything about that.

Mr. Taylor—In reply to this question, I may state that at the time I was conducting experiments for our experiment station in Michigan, I made an experiment upon that very point; I used wax in making foundation when it was at a very low temperature, just as low as it was possible and get to press it at all properly, and also at a high temperature, and I compared them and I could see no difference in the results. One seemed to be worked out just as well as the other.

Mr. Rankin—I would like to ask Dr. Mason how many sheets of foundation of the Langstroth size he says he gets to the pound with a Given press.

Dr. Mason—That depends altogether on how thick I make the sheets. From 4 to 10 sheets.

Mr. Taylor—You can make them 4 or 11, just as you are a mind to.

Continued next week.)

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Drones in Worker-Cells.

Last fall I bought a 5-banded queen, and after commencing to lay I noticed that about half of her brood in worker-cells were drones. Do such queens ever get over this drone-laying business? Or should I take off her head at once? She appeared to be laying less drone-eggs and more worker-eggs after being in the colony a few weeks.

MASSACHUSETTS.

ANSWER.—It sometimes happens that a young queen, or one that has been thru the mails, lays more or less drone-eggs in worker-cells, and afterward lays as a good queen ought. Don't be in too much of a hurry in deciding against her.

Bees Leaving the Brood-Chamber—Best Hive for Extracted Honey, Etc.

1. I have had bees for four years in Langstroth hives, and they always have been breeding below, but this year they all went up into the supers; some hives had no bees and no honey below at all. We had a very hot summer. Was it too hot for them below?

2. I am working for only extracted honey. Which is the best hive for the purpose.

3. Should I use a hive with 8 or 10 frames? and what kind of frames are the best?

4. My best honey-flow is in September, and the first part of October. From what flowers could that be?

5. In what hive can bees be handled the best and the easiest?

NEW JERSEY.

ANSWERS.—1. The heat would hardly account for the bees going above, for generally it is warmer above. In the cases where there was neither brood nor honey below, it looks as if they might have had the super or upper story all winter. In that case, they might move above in the spring because it is warmer above.

2. There is probably nothing better for you than the Langstroth size of frame.

3. For extracted honey, you will like ten frames better than eight. As already said, the Langstroth size of frame, 17½x9½, is not excelled. If bee-glue is not troublesome in your locality, you may like the Hoffman frame, but if bee-glue is plenty, it will be better to have frames spaced with staples or nails. For extracting-frames it is better to have in the upper story shallow frames not more than 6 inches deep. The objection is that such frames can not be used in the brood-chamber.

4. Hard to tell without being on the spot. Possibly aspers or goldenrod.

5. There isn't much to choose. Perhaps nothing better than the common dovetailed hive. Remember it isn't the hive that makes a difference so much as the man, the locality, and the bees.

Managing Swarming in Out-Apiaries—Bees Fanning at the Hive-Entrances.

1. On page 808 (1900) "Ind." asks how you run your out-apiary for comb honey. You say your latest plan was to visit the yard from 5 to 7 days. How do you go to work then—take out every frame and see if there are any queen-cells on them? And then you say, Destroy the eggs or grubs so as to keep them from swarming. I should judge that that would be quite a job, to look over an apiary of 100

colonies or so. Now, some bees will swarm without having their cells capped; where will your swarm be if you don't go there within 5 or 7 days? Anyhow, the queen would be gone. As I understand that you clip your queens' wings, I think it would be the safest way to have somebody right along with them.

2. Why are there always some bees fanning at the entrance? Some say it is for ventilation. I hardly agree with that, because my bees had a flight yesterday, and then some were fanning. If that is to cool the hive, what are they going to do when it is about 100 degrees in the shade?

ILLINOIS.

ANSWER.—1. You are right; it is quite a job to look thru a lot of hives for queen-cells; you are also right in thinking it would be a safer plan to have some one watching for swarms. But it would be a good deal of expense to have an extra hand at each apiary to watch for swarms. Of course, there's no law against others having a watcher on hand all the time.

Yes, some colonies will swarm, and the swarm will be right there in the old hive (except in a few cases where it may enter another hive.) Then the thing needed is to destroy the extra cells, or in some way provide against a swarm issuing again.

I'm not insisting that the plan is satisfactory, and as soon as I learn something better I'll drop the present plan.

2. In nearly all cases bees ventilate at the entrance for the purpose of changing the air in the hive. Even if the air was none too warm it might need changing on account of its impurity. In the case you mention it is just possible that the air in the hive was warm or foul, notwithstanding the fact that the outside air was not above 50 degrees. After being confined to the hive quite a number of days, the bees may become very much excited upon the occasion of a flight, and that excitement may run up the inside temperature above the desired heat. It is quite likely, however, that you had one of the exceptional cases in which bees ventilate without any need of ventilation. I'm not certain whether the books tell about it, but one may often notice a bee ventilating at the entrance because it has accidentally got to the wrong hive, or for some reason is afraid of the reception it will get. A bee afraid as to its reception fails to ventilating, apparently because it thinks it will show it is willing to go right to work helping as one of the members of the colony, and ventilating is the first work that comes to hand. When a strange bee goes to ventilating it is not likely to be ill-treated by the guards.

Grading Honey by Tinted Glass.

I notice on page 88 some comments on the grading of honey by color, by the use of tinted glass, and I wonder if the idea originated among the British bee-keepers. It was advanced something like a year ago in the columns of the *Progressive Bee-Keeper*, and, by following instructions there given, by the use of a number of glasses of different tints it can be graded by numbers from the darkest buckwheat to water-white.

NORTH CAROLINA.

ANSWER.—Yes, perhaps as long as two or three years ago, there was some discussion in American bee-papers as to the matter of grading by samples of glass, celluloid, etc., and the British idea may have started from that, or it may have been an indigenous product. At any rate, our British cousins seem to have gotten the start in the matter of actual application.

Does Sweet Clover Cause Bloat, or a Bad Flavor in Milk or Butter?

Does a sweet clover ever bloat cattle or sheep as alfalfa or red clover does? Does sweet clover give a bad flavor or odor to milk or butter?

NEBRASKA.

ANSWER.—I do not know why, under favorable circumstances, sweet clover might not cause bloat as well as alfalfa or red clover, but I do not remember seeing any report of the kind, nor any report as to its giving bad taste to milk or butter.

Worker-Combs Rejected by Bees.

I have a large quantity of good worker-combs, but being empty and in use, they were laid aside for a season in a damp place. On this account they got hard and

brittle. The bees now reject them, tho placed in the very center of their hives on a warm summer day. They pass over them, or destroy them. Can any one suggest a remedy? Is there any way to soften them, or make them acceptable to the bees?

ONTARIO.

ANSWER.—I don't know of anything to help, if the combs are so bad that the bees destroy them. Who does?

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

POLLEN AND HONEY AT THE SAME TIME, ETC.

Most of us know, notwithstanding scientific doubts thrown at us, that bees often gather both nectar and pollen at the same time, but I suppose few had right in hand the *positive* proof to reply with which a scientist would require. I am glad Mr. Davenport is able to say he has taken hundreds of bees laden with both. I see no reason why a good colony scant of stores might not be given a super of unfinished sections in a warm cellar. Glad to hear that this style of feeding marks well on a considerable scale. If honey that has been fumigated with bisulphide of carbon will kill a colony of bees in the cellar, said honey is pretty sure to be of no particular good to delicate human stomachs. That experiment ought to be repeated until we know whether the death of the bees was from poison or from fortuitous circumstances. Page 776.

SELECTING A HOME BEFORE SWARMING.

"Rip" is undoubtedly right that bees do not *always* select a home before swarming. We may suspect as much when they have a long distance from the home hive, and take a decidedly different direction when they start again. Also when a prime swarm comes out on a desperately hot afternoon, with little or no preparation visible in the hive. It is not likely that invisible preparations have been going on when there were no visible ones. That virgin queen got so tired in flying 50 feet that it took three days to rest her enough to start again, the "born-tired" record may be conceded to her, altho some human parlor-virgins could doubtless run her close. Page 777.

HONEY-DEW IN WINTER STORES.

McEvoy's experiment of wintering with honey-dew is instructive, especially that part of it where part of the combs held good honey, and the bees lived somewhat longer for it but perished eventually. Page 779.

CORKING A HONEY-FUNNEL.

The cork on a wire to stop and unstop a honey-funnel from the inside looks like one of those trifling but very valuable little inventions which sometimes come along. Page 787.

SILVER LINDEN NOT GUILTY OF KILLING BEES.

Notwithstanding the reliability of the journal that makes the accusation, I strongly think the silver linden is not guilty of killing the bees. Bees died of disease otherwise contracted while the accused tree happened to be in bloom, I think. Such disease need not be much different from the one sometimes called "footing it," when we see multitudes of bees not able to fly crawling on the ground about the apiary. It is not impossible, moreover, that the same fungus which injures the lindens, and keeps them from yielding as they used to do, also injures the bees, which get more or less of the spores of mycelium. Page 788.

BURNING COMB TO SETTLE A SWARM.

Most of our veterans will smile at burning comb to make a swarm settle. And yet more unpromising things than that *have* been known to turn out well. In famine times the *other* flying bees of the apiary would be drawn by the smell of wax; and a swarm long on the wing might come, not to the smell, but to the crowd. For just once in their lives the bees belonging to the swarm don't want to gather anything—or do anything except "sciuggle." At least that's the "orthodox" view of it. Page 788.

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly ex-

plained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GENERAL ITEMS

The "Know It All" Kind.

I have been trying to get new subscribers to the American Bee Journal, but the bee-keepers around here seem to "know it all," tho they find there is something lacking when they compare their honey-yield with mine, which is usually two or three times larger than theirs.

H. C. BINGER.

Shiawassee Co., Mich., Dec. 29.

Bees in the Cellar.

My 36 colonies of bees have been in the house-cellar since Nov. 17th, with the temperature from 38 to 45 degrees. The bees are quiet and dry, and there are perhaps a quart of dead bees on the cellar-floor. I have been looking at the bees and their workings thru a low-power magnifying glass, and feel that what a high-power microscope would reveal must be wonderful. The bees and the bee-hive are a constant source of wonder and surprise to me.

F. W. HALL.

Sioux Co., Iowa, Dec. 25.

Bees in Fair Condition.

I commenced keeping bees two years ago, getting my start from a colony of bees that I found in a knot-hole in the side of the house.

This year was almost a failure here. We secured no surplus, but our bees are in fair condition for winter. I think this locality is all right; I am going to give it a fair trial, anyway.

The American Bee Journal is just what every bee-keeper needs in his business. Success to it.

DAN N. HASKIN.

Lancaster Co., Nebr., Dec. 21.

Gathering Pollen and Nectar.

During the forepart of the past season we had such a drouth as was never known here before. Bee-keepers, as well as those in other lines of business, were very much discouraged, and expected very little profit but the July and August rains brought new life, and the result was better than expected.

My yard contained 29 colonies, spring count. They increased to 50, and stored a surplus of over 1,000 pounds.

On page 776 (1900), Mr. Davenport refers to a statement made some time ago, that bees do not gather both honey and pollen on the same trip. I noticed the same statement, and thought if it were true at all it most certainly was not universally so. My observation confirms what Mr. Davenport says. I never thought of making a test at the hive-entrance as he did, but have observed closely the bees on the honey-pollen flora. Their every movement and appearance were convincing that they were loading with both honey and pollen. This was especially noticed on the bloom of the high bush cranberry. This bloom is a cluster formed by a number of small blossoms, whose petals touch each other, forming a beautifully arch sur-

face. The place is a little paradise for the bee, which moves from cup to cup sipping, and apparently making the same movements as when gathering nothing but nectar. At short intervals it rises, works its legs as when placing pollen, and then alights again on another part of the cluster, only to repeat the movements. The light-colored pollen is plainly seen, and the fact that the bee is intent on sipping from every bloom it comes to is evidence that it obtains at least some nectar.

E. S. ROE.

Todd Co., Minn., Dec. 20.

Very Poor Season.

The past season was a very poor one for me. Bees did not do anything after July 1st, but what honey I did have was fancy, and I got a good price for it.

I should be lost without the American Bee Journal.

J. L. HAIGHT.

Delaware Co., N. Y., Dec. 20.

Heavy Loss on the Cotton Crop.

My bees did fairly well the past season, but I lost my cotton crop by the overflows. The loss amounted to about \$1,500. The crop was overflowed on two occasions in September, and again in October.

J. D. GIVENS.

Delaware Co., N. Y., Dec. 20.

Sainfoin - A Brewery Plant.

I notice Mr. Dadant mentions sainfoin, or esparcette, or Holy hay, as a honey-plant in France. I have conversed with an Irishman about it, and he says that in Ireland it yields great quantities of nectar, and is an excellent fodder-plant. I would like to know if any bee-keeper in America has had any experience with this plant,

We Can't Give Away Anything

MODERN REMEDY COMPANY, KEWANE, ILLINOIS.

• [This company will do exactly as it promises.—Editors.]

and if so, I wish there might some day be published an article giving his experience with it.

We have a honey-plant here that is a good one. It is a biennial, and has only a few long narrow leaves the first year; the second year it has a long stalk and commences to bloom. The flowers are blue, and from June until frost you should see the bees on it; I have heard them fairly shouting over it, like a lot of schoolboys just let loose. I do not know the name of it, but the flowers are not larger than a Canadian five-cent piece. I have seen them growing only in two places in Canada, and it seems to me we must have gotten them in some brewery refuse in some way, as they were growing around breweries.

W. D. HARRIS.

Ontario, Canada, Dec. 21.

Did Fairly Well.

Bees did fairly well in this locality. I secured about 4,000 pounds of comb honey from 57 colonies, with an increase of 20.

C. A. STANNARD.

Lapeer Co., Mich.

A Discouraging Season.

In the spring we started with the expectation of having a good honey season, as our bees were out in good time, and went to work. The weather was warm so that we soon had plenty of bees. White clover bloomed in abundance the last of May, but the bees did not store any honey from it. Basswood has been our main source for honey, but the worms destroyed that year or two three years ago, and last fall they stripped the trees of their leaves again. Our crops this season run all the way from 0 to 50 percent of a crop, so far as I can learn of my bee-keeping neighbors. Some sell their comb honey at 10c per pound, and the extracted at from 5 to 8 cents. It is hard to keep up a home trade where we run across some one else peddling it at 50 cents per gallon, and three sections for 25 cents. I get 8 cents per pound for extracted honey, and that is the only kind I have.

F. C. SMITH.

Pierce Co., Wis., Dec. 19.

A Successful Beginner's Report.

Two years ago I became interested in bees by hiving a large swarm that alighted near my home. I put them in the back yard and began to study their habits. I found the subject so interesting that I gave it all my spare time. Not knowing exactly how to care for them, the first winter killed so many that I started in the spring with only a handful, and it was all they could do to get ready for last winter, but they came thru in fine condition. I took off the first surplus honey (28 pounds) last summer, and fixt them for this winter leaving them about 35 pounds of honey. I use the 10-frame Langstroth hive. A bee-keeper living near here who saw the bees last summer said it was the finest colony he had ever seen. Having just the one colony, and buying the very best of everything, I was able to keep it as neat as a pin, and I also profited by the valuable suggestions found in the American Bee Journal. As soon as possible I hope to increase to 3 colonies, which will be as many as my business will allow me to care for.

Are You Making Money?

—Out of your poultry we mean. If not there is something wrong. Maybe you didn't start right. We have published a book called the **20th CENTURY POULTRY BOOK** which helps to start poultry people right and then keeps them right. Tells all about the business and about the best—THE RELIABLE INCUBATORS AND BROODERS. They are used all over the world. The book will be sent on receipt of 10 cents as long as the supply holds out. Better order at once. **Reliable Incubator & Brod. Co., Box B-2, Quincy, Ill.**

The Ohio Farmer —AND THE— American Bee Journal,

Both One Year for only \$1.40.

THE OHIO FARMER is clearly one of the leaders of the agricultural papers of this country. It is a 20-page weekly, often 24 pages, handsomely printed on good paper, and **CLEAN** in both reading and advertising columns. It has the largest actual staff of editors and correspondents (all farmers) of any farm paper published, and is practically progressive in defending the farmer's interests.

IT WILL HELP YOU MAKE "THE FARM PAY." Send to **OHIO FARMER**, Cleveland, Ohio, for a free sample copy.

REMEMBER, we send both the Ohio Farmer and the American Bee Journal, both one year for only \$1.40. Address,

GEORGE W. YORK & CO., 118 MICHIGAN STREET, CHICAGO, ILL.

The "Barler Ideal" OIL-HEATER

**Saves Its Cost Every Year!
NO ODOR! NO SMOKE! NO ASHES!**

Costs only a cent an hour to run it.

The editor of the American Bee Journal is using the "Barler Ideal" Oil Heater, and it is all right in every way. We liked it so well that we wanted our readers to have it too, so we have recently arranged with its manufacturers to fill our orders. The picture shown herewith is the one we recommend for general use. It is a perfect gem of a stove for heating dining-rooms, bed-rooms, and bath-rooms. It hinges back in a substantial way, and is thoroughly well made throughout. The urn removes for heating water. The brass fount, or well, has a bail, and holds nearly one gallon of kerosene oil. It is just as safe as an ordinary lamp. You wouldn't be without it for twice its cost, after once having one of these stoves. Most oil stoves emit an offensive odor, but this one doesn't. Its height is 2½ feet, and weighs 20 pounds, or 30 pounds, crated ready for shipment, either by freight or express.

Price, f.o.b. Chicago, \$6.00; or, combined with a year's subscription to the American Bee Journal—both for only \$6.50. FULL DIRECTIONS GO WITH EACH STOVE.

If you want something that is really serviceable, reliable, and thoroughly comfortable, you should get this "Barler Ideal" Oil Stove, as it can easily be carried by any woman from one room to another, and thus have all the heat you want right where you want it.

Address,

**GEORGE W. YORK & CO.,
118 Michigan St., Chicago, Ill.**

No. 4 "Barler Ideal" Oil-Heater.

Please mention the Bee Journal when writing Advertisers.

The white clover was a total failure here last summer. All the honey our bees stored was from sweet clover which is very abundant in this locality. The late Mr. Muth, I believe, is given the credit of being the one who covered our clay and stony hills with it.

Altho I am only keeping bees for the enjoyment I derive from it, I could not have succeeded as I have without the help of the Bee Journal.

A. W. MACBRAIR.
Hamilton Co., Ohio, Dec. 19.

A Hard Season For Bees.

Owing to continued wet weather the past season was a hard one for bees in this country, tho nearly all bee-keepers secured a little surplus, and very few had to feed for winter, so we ought not to complain. Some localities had a fair crop.

From 30 colonies spring count I increased to 40 and took off 900 pounds of surplus honey. Only about 600 pounds were finish sections, and I had about 600 unfinished sections.

In most places in this country bees went into winter quarters rather light in bees, but a good quality of stores. Like all good bee-keepers I am looking for a good season next year.

I like the idea of printing each week on the front page of the Bee Journal a picture of one of the leading bee-keepers. I always read an article with more interest when I know what the author looks like. The pictures of the different apiaries from all over the country are also a very interesting feature to me. Keep the pictures coming, even if you have to ask a little more for the Journal. In fact, I think you are giving us a most excellent paper for the price we pay for it.

O. B. GRIFFIN.

Aroostook Co., Maine, Dec. 15.

Loss From Diseased Brood.

This has been another bad year for bee-keepers in this part of the country. Foul brood, black brood, or pickled brood—call it what you may—is doing its work. It looks the same as the comb of infected brood shown at the National Bee-Beekeepers' Convention in Chicago last August. I had nearly 50 colonies and nuclei affected with it. I treated them according to the McEvoy plan, but the disease reappeared in some colonies, while others dwindled away in spite of my efforts to strengthen them. The "glue-pot smell" was absent in all cases, but the dead brood was sour, and had a very offensive odor after it commenced to turn black. There were only two colonies in which I detected the "glue-pot" smell, and in which the decayed matter had become roapy.

I purchased 11 colonies and transferred during fruit-bloom, and at that time there were no signs of the disease. In June I detected the disease among them, and by fall all were dead. I sacrificed several good colonies trying to build them up.

Not one of the infected colonies stored any surplus, but twenty colonies alongside which were not infected, stored from 20 to 60 pounds per colony of beautiful comb honey.

The disease first appeared here in

Sharples Cream Separators; Profitable Dairying

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underside the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it, but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your Pocket-Knife will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us three new subscribers to the Bee Journal (with \$3.00). We will club the Novelty Knife and the Bee Journal for one year, both for \$1.00.

YELLOW OR WHITE

Sweet Clover Seed

Free as a Premium

For Sending us One New Subscriber for a Year.

There has been so much written about both the white and the yellow variety of sweet clover, that we will simply say here that if one of our present regular subscribers will send us \$1 with a new name for this year, we will mail, postpaid, to the one sending the new name and the dollar, either **one pound** of yellow sweet clover seed, or **two pounds** of the white sweet clover. This is a good chance to get a start of both kinds of these honey clovers. Better send two new subscribers (with \$2.00) and get the three pounds of seed. Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO, ILL.

Weekly Budget

MR. J. A. GOLDEN has an advertisement on page 46, offering his stock of Golden combination hives for sale. Better write him at once if you want to try his system of producing comb honey.

JOHN H. MARTIN, better known as Rammer, has been keeping bees for some time in Fresno Co., Calif. He is now in Los Angeles county again, and wrote us as follows, Dec. 24th:

"I have returned to the south after a successful season in central California. There was a grand rain here about Nov. 30th, but since then the skies have been clear. Beesmen who smiled broadly then now look sober. It is time for another rain, and if it does not come soon there will be a lot of blue beekeepers. It is the old, old story—the bee-men here never know where they are at respecting a honey season till well towards spring. After nine months' absence from my old apiaries I find them flourishing, and the bees are anxious for a good honey season. And for which we all devoutly hope."

WALTER S. POWDER, of Indianapolis, Ind., writing us Jan. 4th, had this to say:

"I regret exceedingly that you have been so unfortunate as to have a fire in your establishment. You have my sympathy, and I hope the loss and inconvenience will be less than expected. I have often wondered what I would do in case of fire here, but in your case, with the Bee Journal on your hands, I know the situation must be very serious and troublesome."

"I have had no bill for my last quarter's advertising, but think the little amount might do you more good right now than later. Find check enclosed."

Thank you, Mr. Powder, for your kind words of sympathy for us in our "flood" of troubles. We hope you may never be visited as we were; but, as the saying is, "a bad beginning makes a good ending," we may end the 20th century all right—tho we will not likely see its end.

O. L. HERSHISER, superintendent of the Pan-American Exposition, wrote us as follows Jan. 8th:

MY DEAR MR. YORK:—A letter from E. R. Root has informed me of your loss, by fire, of the offices of the American Bee Journal. No particulars were stated, but I trust you had insurance protection, and that the only loss to the readers of the American Bee Journal will be some necessary delay. I regret the inconvenience you will be occasioned, but I have no doubt of the future of your excellent publication, even against the scourge of fire. It would be quite an Chicago-like for anything in your enterprising city to be subdued by that or any other calamity. The enterprise of the American Bee Journal is well shown from the fact that, after the office was burned on the evening of Jan. 1st, as I am informed, we had the initial number of the new century before learning of the disaster.

Wishing the American Bee Journal a prosperous century in the hands of its present proprietor, and his successors, believe me, Yours very truly,

OUEL L. HERSHISER.

As noted in last week's Bee Journal, our loss was occasioned by water, that was thrown on the fire which was above us. It was almost a miracle that we were not burned out also.

We wish to thank Mr. Hershiser for his kind letter.

BEST Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough the Alfalfa extracted.

BASSWOOD HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood, blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Either Alfalfa or Basswood Honey:

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are boxt. This is all

ABSOLUTELY PURE BEES' HONEY.

The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:

I've just sampled the honey you sent, and it's prime. Thank you. I feel that I'm something of a heretic, to sell several thousand pounds of honey of my own production and then buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drink, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honeys of more market honey, according to my taste.

C. C. MILLER.

McHenry Co., Ill.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

ESTABLISHED IN 1861 AMERICAN THE OLDEST BEE-PAPER IN AMERICA BEE JOURNAL

41st YEAR.

CHICAGO, ILL., JANUARY 17, 1901.

No. 3.

* Editorial. *

Yellow Wax and Slow Cooling is a subject which receives considerable attention in the first number of the American Bee-Keeper for the new century. Editor Hill seems to understand that this journal teaches that any sample of wax, no matter what its color, and no matter what may have caused that color, may be changed into bright yellow wax by simply cooling it slowly. This journal has never pretended to claim for slow cooling anything more than that it allowed the foreign particles time to settle. The average beginner will have a cake of wax that has been rapidly cooled, and so of dark color because of its impurities. If nothing has been done to affect the color of the wax except the rapid cooling, slow cooling will clarify it. (Of course, it may be made still brighter by acid.) That's the whole thing in a nutshell. The editor of the American Bee-Keeper has emphasized the necessity for slow cooling, and nothing that he publishes in his last number militates with the teachings intended to be given here. It is a regrettable circumstance if lack of control of the English language has allowed any meaning to be given that was not intended.

The Long-Tongue-Short-Tube problem is still on. J. Warren Arthur, in *Gleanings in Bee-Culture*, reports advance at the red-clover end. The interesting details are as follows:

In 1898 I noticed my bees going and coming in one direction, namely, southwest. Thinking to find what they were working on, I followed in that direction, and found very few bees at work on or near the ground, and no timber of any consequence on which they could work. About a mile and a half from home I found a clover-field fairly swarming with bees, while a clover-field of 30 or more acres one side of it, not 50 yards apart, and not more than 40 feet from the remainder of my lot of 30 hives, had very few bees on it. Some two or three days after, I noticed the bees stopping about noon, and taking my wheel I rode around and found my clover-field laid low. When the second crop came in bloom I again noticed the bees in particular, and found them working on this same field, altho the field across the road from my home contained many more bees than on the first crop. This fact alone caused me to decide that I wanted seed from that particular field. When the neighbor hulled his seed, by offering a few cents above the market price, I obtained it, but had to take the entire crop to get any. I managed to sell some of it to some of my neighbors, and some more to my father, who lives about ten miles southwest of me. The crop of seed sown near me in 1899 was almost a failure in catching, and what did

catch was winter-killed last winter, while some fair fields were left over at my father's.

My prospects for honey last spring were anything but bright for 30 colonies, so I decided to divide up territory. I took five of my weaker colonies and one strong one to my father's; four were taken to a place where there were a fair number of basswood trees, altho badly cut by the canker-worm. Well, this fall I had 24 colonies to feed, nearly all being at starvation's door.

My father said when he cut his hay he never saw bees thicker on a buckwheat patch than on his clover. I made a trip to see how they were doing, and had the pleasure of helping him haul up his hay; but when that clover-field bloomed for seed, those bees filled up everything tight; and I was surprised, on going down one day, to find them so. Now, I feel that that clover had something to do with it. But the weakest colony taken down there built up the strongest, yet could not have been fuller of honey than the other five.

It has been suggested in *Gleanings* that wherever there were bees with tongues long enough to work on red clover there would be seed matured on the first crop. The possibilities that lie in this suggestion are worth considering. It is well known that seed from red clover is secured only from the second crop, altho the reason therefor is not so well known. It is a very simple one. The fertilization of red-clover blossoms is effected mainly by bumble-bees. Unlike our hive-bees, bumble-bees start in the spring, not with several thousand bees in a nest, but with a single bee. So when the red clover first blooms, bumble-bees are so few that not enough blossoms are fertilized to make a crop of seed worth harvesting. By the time the second crop is on, the number of bumble-bees has multiplied many times, and a full crop of seed is secured.

Now, if hive-bees are secured with tongues long enough to work on red clover, it is easy to believe that they may fertilize the first crop. From this first crop it will be easier to obtain seed of the short-tube kind. A little explanation will make this clear. In the second crop of red clover there will be tubes of various lengths. Hive-bees may work on the shortest of these, and bumble-bees on the rest. So it will happen that the seed from this crop will produce blossoms having tubes of different lengths, with perhaps a constant tendency to revert to the original and longer type. Only by difficult and careful selection under such circumstances could a fix type of short-tube clover be secured.

Now, instead of waiting for the second crop, let full attention be given to securing seed from the first crop. The hive-bees will fertilize the blossoms with short tubes, and those with long tubes will for the most part be unfertilized. So whatever seed is secured from that first crop will be of the short-tube kind. The next year it will produce red clover with

blossoms, all of which can be utilized by the hive-bees, and by saving seed each year from the first crop the long tubes will be automatically weeded out.

Tin Cans vs. Barrels for Honey.—We think most of our readers are aware that we strongly favor tin cans for holding honey. And we have not come to this conclusion hastily, but after considerable experience with handling honey in both kinds of packages. We are free to say that we don't care to handle any more honey in barrels, no matter what the grade of honey is.

Some of our good friends in Wisconsin—which, by the way, is a great barrel State—enjoy opposing our stand on the can, of course doing so in a good-natured way. But it is our turn now to refer them to the following, by Elias Fox, of Wisconsin, which appeared in a recent issue of *Gleanings in Bee-Culture*:

I can truly indorse all that was said in favor of tin cans as against barrels for the shipment of honey, at the Chicago convention. I have had quite a little experience along this line myself, and have decided never to use a wooden package for extracted honey again. I began putting it up in wooden packages with wooden hoops; and I found by letting them stand a short time the hoops would loosen up, and, unless watched very closely, and hoops tightened, there would soon be a leak, no matter how good the cooperage; and, even in shipping, the hoops would loosen.

Then I had my cooper use iron hoops, and my experience was the same, by letting the packages stand for any length of time, notwithstanding we selected the choicest and most thoroughly seasoned staves and the cooperage was perfect; and the packages were made up a year before using and kept in a dry place, and hoops retightened, and filled dry. If there was a piece of heading a little cross-grained the honey would ooze thru the pores, and even thru the end of the staves, and almost invisible knots, no larger than a pin-head. Of course, so far as the loss was concerned from leaking, it was nominal. But if you count the amount of honey absorbed by the wood, and the leakage together, it would equal, if not overbalance, the difference in the cost of the two packages.

Then, again, think of the nasty, sticky packages to handle, and hands and clothes daubed with it; and when barrels are in this condition, and rolled along, as advocated, dust and dirt will stick to the leaking spots, and make an unsightly package, and from sneering depot platforms and car-floors, to attract bees, flies, etc.

The barrel side of the debate say if a case is dropped, the solder will loosen, and a leak would result, and that the cans are not so unwieldy and too heavy to handle. A man should not be so awkward as to drop a package. But suppose he is, and the package should be a barrel. About the time you had it up to the wagon-box, and the head should burst out, which would leak the worse? As to the cans being a little too heavy, I would say they are; yet I have moved, alone, 5,000 pounds in two-can cases in a day; had ten rods to carry it to the

wagon, two miles to haul it, and piled it up five cases high, and my consolation paid me for the extra work in knowing there was not a drop of leakage, and no hoops to loosen while I slept.

We can not be too neat in handling and marketing extracted honey. So I say, give me new 60-pound cans, and I will guarantee my honey to reach *any* market in such a condition that I shall not be ashamed of it, and no loss from leakage or absorbing. If we want a *cheaper* package for dark honey, there are plenty of second-hand cans and cases to be bought as cheaply as barrels.

We welcome Mr. Fox to the tin-can side of the debate; and if he will only be present at the Madison meeting of the Wisconsin State Bee-keepers' Association, on Feb. 4th and 5th, next month, we (Mr. Fox, Mr. Hatch and ourselves) will simply "do up" those wooden-headed-barrel chaps, like Messrs. Pickard, Wilson, McNay, and others. Of course, we'll treat them square(ly), but will see that they don't roll any of their honey-soak and leaky-daub wooden barrels over us! We'll just honey-can those boys so that they'll keep like any other kind of canned goods.

The Case of Uter vs. Uter.—As mentioned in a former number, we give this week something further about the celebrated peach-bee case of Uter vs. Uter, which came to final trial at Goshen, N. Y., Dec. 17, 18 and 19, 1900. Gleanings in Bee-Culture contains quite a full report of the trial, from which we take the following, written by Editor E. R. Root:

The case was a peculiarly hard-fought one; and after 25 or 30 witnesses had been examined on both sides the jury brought in a verdict, after being out about ten minutes, for the defendant, bee-man Uter.

I need not say that the National Bee-keepers' Association took an active part in this case—one that seemed to involve the very life of bee-keeping in New York. It pledged \$100 to Bacon & Merritt, two of the leading attorneys of Orange County—lawyers who have been retained in some of the most important cases that have been tried in that vicinity.

There were many laughable incidents, and some queer statements on the part of the witnesses for the plaintiff, as to how the bees did and could puncture fruit; how they used their "horns" (antennae) to make holes, etc. In the lower court, several of the witnesses, I am told, testified that the bees got up "on their hind legs" and *stung* the fruit; went off and left the peach, and stung others; that a rotten spot at the points pierced by the stings would soon set in, and this would be subsequently visited by the bees. In the higher court, that same set of witnesses testified that the bees punctured the fruit with the "head end," and not with the "business" end. It was evident that the prosecution had realized the utter absurdity of the former statement. The plaintiff, fruit-man Uter, while on the stand, went on to describe how the bee moved its head first to one side and then the other, and raised up on its legs and flopped its wings; that after this performance he found there was no hole. This was contradicted with some variation by his two sons. It was amusing to see the plaintiff try to nudge the bee, on the witness-stand, as he swayed his head from one side to the other, raised up on his legs, and flopped his arms. His motions were so utterly ridiculous, and so contrary to the real acts and movements of bees, that every one in the courtroom, including the jury, laughed, and laughed heartily. I sincerely believe that, if the jury had gone out at that supreme moment on the evidence then presented, we should have had a verdict in our favor, even without one word of rebuttal testimony.

Another witness, Mrs. W. H. Uter, the wife of the plaintiff, testified that the bees went right on the fruit, and then with their "horns" make holes in the peaches. She stated that there were eight holes in one peach she examined, and that three bees were

on it; that after they left, there were three more holes, or eleven in all. Mr. Bacon, one of our attorneys, in his cross-examination, got at this, something in this way:

"You say, Mr. Uter, that there were three holes after three bees had visited that peach?"

"Yes."

"You say that the bees made three holes with their horns?"

"Yes, sir."

"Where were these horns located?"

"On the top of the head."

"Two prongs like this," said he, putting his two hands over his head.

"Yes."

"And they took those two horns and dug them right down into the peach, did they?"

"Yes."

"Now, Mrs. Uter, will you tell the jury how three bees, each with two horns, could make only three holes? Shouldn't there have been six holes?"

"Wy-ah, wy-ah, wy-ah; they took those two horns and put them together and then poked them into the peach."

O—h!" said Mr. Bacon, with a wise look. At this point an hour of laughter.

When the jury and the audience had subsided, Mr. Bacon continued:

"You are sure the bees made these holes with their horns?"

"Yes."

"Well, don't you know that those are antennae, or feelers?"

Several had talked about the so-called "horns," and how bees make holes with the horns; but after the learned counsel had shown the Uter absurdity of the horn theory, then the prosecution began to talk about the "jaws;" and some of the witnesses told how the bees ran their "bills" down into the peach—meaning, of course, the tongue.

But the bill theory was untenable, and the rest of the testimony was then confined to the jaws, which, it was averred, were powerful enough to puncture the skin of peaches. The prosecution claimed, among other things, that after the bees had punctured the peaches, the juice ran down on the limbs, causing them to wither and drop. In the former trial it was maintained that the trees were utterly destroyed; and even in this trial the Peach Uter at first talk of the destruction of trees, and claimed damage for the loss of trees and fruit. The defense, on the other side, showed by two good witnesses that the plaintiff, Mr. Uter, the fruit-man, had said to each of the witnesses that these trees were going to die, and he would have to pull them up, and this was *before* the bees are alleged to have visited the fruit.

I do not need to rehearse here the testimony that was introduced by expert bee-keepers, who I can not omit reference to the testimony of Prof. Frank Benton, Assistant Entomologist, Department of Agriculture, Washington, D. C. Prof. Benton had been sent by the National Bee-keepers' Association to render expert testimony on the mouth parts of the bees, and he certainly was the star witness for the defense. He showed by live and dead specimens of bees, and also by charts which he had brought for the occasion, that it was impossible for the bees to puncture fruit with their mandibles or jaws; that the jaws of bees were very different from those of wasps and other insects having cutting edges or teeth. He chloroformed some live bees, and then past them around to the jury, after our attorneys had objected to their use from the court to do so. He showed them that the delicate tongue, so far from being a "bill" which could puncture a sound peach, was more like a camel's-hair brush; that it would be absurd to suppose that they would run this thru the skin of any substance. He admitted that bees could tear by picking away at them, but denied the possibility of their *cutting* the skin of any fruit. The jaws, or mandibles, had smooth rounding edges, which, he showed by charts, were different in this respect from the jaws of a wasp, that has cutting edges or teeth; that the mandibles were made for forming plastic substances like wax, and even then they were had to be brought to a temperature of about 90 degrees before wax could be performed.

The professor's testimony, so far from bearing evidence of prejudice, was what might be

termed in legal phraseology, "candied." The kind that weighs with a jury. There was no evasion, and no attempt on his part to make *all* of his testimony in favor of the bees. When asked whether he regarded the experiment of confining a few bees in a box with a peach as worth anything to prove that bees would not or could not puncture sound fruit, he said that, in his opinion, it did not count for much, as he doubted whether they would even help themselves to honey under like circumstances.

At the conclusion of the testimony for the defense, the prosecution called Peach Uter back to the stand, and asked him whether the trees, the fruit of which the bees were alleged to have stung, causing the limbs to die, were alive and in good order. He said yes, in very good order. This testimony was produced, probably, to show that the trees did not have the "yellows," or "wet feet," as was claimed by the defense. But Mr. Bacon, in his final plea before the jury, called attention to the fact that the plaintiff first testified that his trees had been *destroyed*, and that now they were *good and sound*; and yet he desired compensation for the trees which he at first said were *destroyed*. Mr. Bacon made a strong plea, picking up all the important threads of evidence, and hurling them at the jury in a most forcible manner.

The attorney for the plaintiff, while he did not attack the testimony of Mr. Benton, turned his guns upon A. I. Root, shaking his fist in his face, and calling him a "poo-bah," "poo-bah" of the West. A. I. R. did not appear to relish the compliment; but the rest of us enjoyed the joke immensely, tho there wasn't one of us who knew what "poo-bah" meant. We consoled A. I. by saying that it signified something big, and told him not to feel badly.

Of course, no one could tell absolutely what the jury would do; but it seemed to be made up, if I could judge by their faces, of a lot of intelligent, thinking men.

The judge, in his charge, rehearsed very carefully and impartially the full case, and then said that the jury, in order to render a verdict for the plaintiff, must find that the trees of the defendant, Mr. Bacon, *were* destroyed; and that if the jury should find otherwise, they were the trespassers; and that if the jury should further give very careful consideration to expert testimony. The jury then retired, and in about ten minutes returned with a verdict of "no cause for action."

The National Bee-keepers' Association exerted a powerful influence in the case, inasmuch as it enabled Mr. Uter, the bee-man, to employ the best legal talent, and, in addition, furnish expert testimony on the bee-side of the question, so that an unprejudiced jury, seeing and knowing the facts, would render a verdict accordingly.

This case was a hard-fought one from beginning to end. There was no lack of legal counsel on either side, and no lack of witnesses; but, thanks to the Association, we were able to show that the evidence adduced by the plaintiff was, for the most part, to put a most charitable construction on it, founded on misapprehension, ignorance, and prejudice. There is no doubt that some functions for the fruit-man were defeated, in that the bees did puncture sound fruit with their "horns or bills." If they did so believe, and if they heard our evidence, their belief must have been most severely shaken before they went away.

The Delay and Interruption to our business, occasioned Jan. 1st by the water poured on the fire above us, and which landed on our stock, will be over by the time our readers receive this copy of the Bee Journal. By another week we hope to know just what and how much of the bee-supply stock was damaged by water. Some of it is a total loss, some slightly damaged, and some still in good condition by having been well protected with tarpaulin covers.

We are not anxious to have another such dampener put on our place of business. While it thoroughly settles the dust, it also quite as thoroughly unsettles things too much. However, trials and tribulations are the common lot of man and perhaps we are getting only our share.

The National Bee-Keepers' Association.

General Manager Secor's 4th annual report was sent to members of the Association last month with a voting-blank for the election of three directors and general manager. Mr. H. F. Moore and the Editor of the American Bee Journal were selected as the committee to receive and count the ballots. The result will likely be known in time for announcement next week.

In order that General Manager Secor's report may have a wider circulation we give it here:

FOURTH ANNUAL REPORT OF THE GENERAL MANAGER OF THE NATIONAL BEE-KEEPERS' ASSOCIATION.

FOREST CITY, IOWA, Dec. 11, 1900.

Fellow Members:—At the last annual election of general manager and directors, Dec., 1899, the question of uniting the two National societies was submitted to the members of both organizations, and the new constitution, which slightly changed the name of our society, was ratified and endorsed by a large majority of both old societies. It is therefore gratifying to report that what some thought to be two rival associations with similar aims have united, and the increased interest augurs well for the now-named "National Bee-Keepers' Association."

There is no doubt about the usefulness of such an organization, if properly managed. The question of its efficiency under the present management is pertinent, and every member may rightfully express his confidence or his criticism by his vote, or in any other proper way. The present manager does not pretend that his judgment is infallible or that the efficiency of the organization can not be increased by other management than his own. But this much he does claim—to have honestly and faithfully discharged the duties imposed to the best of his ability.

The board of directors and all other officers of the Association have heartily co-operated with the general manager in the business in hand, and therefore entire harmony prevails, so far as this writer is informed.

The kind and appreciative words received from time to time from members of the Association and friends generally are prized beyond compare. They are like sweet flowers found in desert places where one expects nothing but the hard thorns of bitter opposition. It is easy to labor when one is cheered on by encouraging words.

I have not in every instance been able to help those who have appealed to me. Some cases have been too hard. For example, it is not possible to collect a bad debt if the debtor is bankrupt and execution-proof, with no disposition to pay. Dishonest honey-dealers will sometimes evade their debts and escape punishment just as a thieving bank-teller will occasionally squander the savings of depositors and go scot-free. The suggestion is here emphasized that it is better to look up the financial rating of every man who buys honey, and the honesty of every commission man, before making a consignment, rather than try to recover a bad debt hastily accepted.

THE CASE OF UTTER VS. UTTER.

Several months ago, in the County of Orange, New York, two brothers fell out, the one a grower of peaches and the other a bee-keeper and member of this Association. The peach-growing Utter sued the bee-keeping Utter before a Justice of the Peace, and asked for damages done to plaintiff's peach-orchard by defendant's bees. The case was tried, and after a good deal of damaging evidence was introduced by the plaintiff, and astounding revelations as to what bees could do and did to those peaches were heard, the learned judge decided against the bee-keeper and assessed him \$25 and costs. While there was a lack of *competent* evidence that the bees were guilty as charged, it seems that the fruit-growers had the sympathy of the court.

The case was sensationally written up by reporters and the matter was given wide circulation thru many papers. The coloring given to it was generally against the bee-keepers.

The Rural New Yorker, however, used its influence to show that bees are not guilty of injuring sound fruit. But a letter from its editor, besides communication from many bee-keepers, convinced me of the alarm that was felt if this decision were left unchallenged. If that case could be quoted in the future it was feared that other bee-keepers might suffer. The general manager, therefore, with the concurrent judgment of a majority of the board of directors, ordered the case appealed to the county court, and it is

proposed there to try the case over again on its merits, with enough expert witnesses to get the facts before the jury.

As the brother who was the defendant in this case is a poor man, and, as in the judgment of the general manager, the matter was one which had to be fought out sooner or later in the interest of truth and justice, he pledged \$100 toward a favorable verdict. The Association will be obliged also to pay the expenses of several expert witnesses while attending the trial. The results can not be ascertained in time to go into this report.

BEES AND HORTICULTURE.

During the past year the general manager has compiled and published a twelve-page pamphlet showing the value of bees as pollinizers and fruit-producers. This was thought to be necessary because there is so much ignorance on the part of orchardists relating to the work done by insects in their interests. Spraying is becoming more and more common. When to spray and what preparations to use are shown, quoting competent authorities. Laws of several of the States in relation to spraying are also quoted.

This pamphlet has been forwarded to several members who feared trouble from neighbors who threatened to spray with poisonous substances while trees were in full bloom, and it is hoped and believed that this timely publication has had some educating influence, because no reports have come to this office of damage done to bees by spraying where it was distributed. It has always been my policy to try to prevent law suits rather than to win them. If by educating the people we can make good neighbors—neighbors who respect each other's rights—it is better than winning victories at the end of bitter legal battles.

The above pamphlet was sent to several agricultural and horticultural journals and in every instance was favorably noticed.

THE FIGHT FOR PURE HONEY IN 1899.

It will be remembered that the Association put up a fight against adulterated honey in Chicago last year. A statement of this matter was in my last annual report. While the outcome of the suit was not satisfactory to us at the time, later developments seem to point to the fact that it had a wholesome influence. The following extracts from Gleanings of Sept. 15, 1900, may be of sufficient interest to warrant copying here. It is as follows:

"At the Chicago convention we had the pleasure of hearing Prof. E. N. Eaton, chemist, and Commissioner A. H. Jones, of the Illinois State Pure-Food Commission. Both of the gentlemen express themselves as being highly pleased to meet so representative a body of bee-keepers assembled for the purpose of discussing ways and means for putting down the adulteration of honey. They told of the work they had already begun; how they had compelled the dealers thruout Chicago (the very hotbed of adulteration only a few months ago) to sell all food products under their legitimate and real names. Samples of honey mixtures were brought in, showing in some cases the word 'pure' had been crost out by the dealer, and the word 'imitation' in plain letters had been written in its place to conform to a recent law enacted at a session of their last legislature. All kinds of honey mixtures, imitation honey, glucosed honeys, if they are sold at all, have either been relabeled or else the word 'pure' has been scratch out and the word 'imitation' in bold letters put in its stead.

"It will be remembered that the United States Bee-Keepers' Association, under the direction of General Manager Secor, and thru the personal efforts of George W. York and Herman F. Moore, (a well-known honey-man and an attorney), gathered up, a year or so ago, a number of samples of bogus honey. These were placed before the city prosecutor, and certain suits were begun against the vendors of the samples. It created quite a furore among the dealers, for the Chicago papers were full of the matter for the time being; and altho the first suit resulted in a verdict of "not guilty" for one of the parties on a queer sort of technicality before the justice, the result of this prosecution, while apparently a failure, was a far greater success than the Association could have hoped for in twenty years. How? Both Prof. Eaton and Commissioner Jones stated before the convention that the suits begun by the United States Bee-keepers' Association made such a stir in the city that it helped in no small degree toward the enactment of the new law now in force and being enforced."

I wish to acknowledge the hearty co-operation of the Division of Entomology, Department of Agriculture. Mr. Frank Reinton, assistant in the Division, has rendered valuable service by replying ably to enquiries directed to the

Department on the subjects relating to bees and fruits, and has put into my hands copies of correspondence in several instances where litigation was threatened, but which was averted by prompt and prudent action.

A CASE AT EVANSVILLE, INDIANA, was reported to the entomological Division stating that the city authorities proposed to pass an ordinance prohibiting the keeping of bees within the city limits and for *four miles outside*. The matter was referred to me, and such literature as was available was forwarded to the attorneys for the bee-keepers, and they were also referred to McLain's experiments. No doubt the matter was dropped by the city, as nothing further was heard of it.

Several other cases have been reported to me during the past year, of cities and towns threatening to rule the bees out, but copies of the celebrated Arkadelphia decision sent, no doubt had a restraining influence.

The general manager has written more than a hundred official letters during the year, besides hectograph copies sent the directors at different times, and besides the regular routine of official notifications and receipts.

Many of these letters have been lengthy legal opinions in answer to members who have been threatened with lawsuits.

The Association sent Mr. Abbott as delegate to the Third annual convention of the National Pure Food and Drug Congress, which convened in the city of Washington, March 7, 1900, and paid a small portion of his expenses. The work of this congress is in the interest of purity and honesty of all foods and medicines consumed by man. It is laboring for the enactment of laws to protect innocent purchasers from deceit and fraud. The board of directors believe such efforts worthy of aid.

THE HAKES ADULTERATED-HONEY TRIAL.

January 22, 1900, Secretary Dr. A. B. Mason, at my request, attended and assisted in the trial of a groceryman at Jackson, Mich., who had been arrested by the State Food Inspector on the charge of selling adulterated honey. The suit was in the circuit court of Jackson county, and it appears to have proven beyond doubt that the honey offered for sale and sold by Mr. Hakes, was largely adulterated with glucose syrup. The court instructed the jury to return a verdict of guilty, which was done. I have no doubt that this trial will have a wholesome effect in Michigan and in all other States where pure-food laws are in force.

If impure extracted honey can be driven from the market, and consumers led to believe that what they buy as honey is really the product of the hive-bee, a better price may be realized by the producer of a first-class article. It may be well to state here that *quality* as well as *purity* is essential. No *unripe* honey ought ever to be offered for sale.

In conclusion I wish to admonish our members to keep out of trouble if possible. Don't get the idea that this Association can do everything. Bee-keepers must keep within the law if they wish to have the protection of law. Bees may become trespassers like other domestic animals, and bee-keepers may be liable for damages done by bees in some instances. It is therefore wise to avoid any conflict with near neighbors which your care can prevent. Infuriated bees in a thickly settled neighborhood may bring legal contests which this Association can not win. The Golden Rule is the highest law. Fraternally yours,

EUGENE SECOR, *General Manager*.

Mr. Secor closes his report with a financial statement showing a balance of cash on hand of \$521.15.

The Association now numbers 560. It is unfortunate that so large a number of bee-keepers have not yet discovered the personal benefit and security there may be for them in uniting with the National Bee-Keepers' Association, yet it is pleasant to know how much has been already accomplished by organization, and the present number of members gives hope that it may continue to increase. There ought to be a large gain in membership with the beginning of the new century, and now is a good time to act.

The American Fruit and Vegetable Journal is just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both for \$1.10.

Convention Proceedings.

Report of the Proceedings of the 31st Annual Convention of the National Bee-Keepers' Association, held at Chicago, Ill., Aug. 28, 29 and 30, 1900.

BY DR. A. B. MASON, SEC.

(Continued from page 24.)

Pres. Root—We are very fortunate in having Prof. Eaton of the Pure Food Commission of Illinois with us, and Mr. Moore, who knows him well, I have asked to introduce him.

Mr. Moore—Mr. President, ladies and gentlemen of the National Bee-Keepers' Association, it gives me great pleasure to introduce to you Prof. Edward N. Eaton, who was formerly chemist to the Minnesota Pure Food Commission. He has been a member of the Chicago Bee-Keepers' Association, and has been very much interested in our work, and is really one of us. He used to analyze samples for us, and the time came when the Illinois State Legislature organized a Pure Food Commission. Under this Commission there must be a chemist appointed. The Chicago Bee-Keepers' Association recommended Prof. Eaton for this appointment. He is now the analyst of the Illinois Pure Food Commission, and I present him to you.

Prof. Eaton—I thank Mr. Moore for his very kind introduction, and the kind words he has to say, and I appreciate them fully. I didn't expect to take up any of your time this afternoon, I didn't expect to make any sort of a speech, simply express to you the gratification I feel in being able to attend this convention, and the pleasure I always have in attending bee-keepers' conventions. This is the first of your national conventions I have ever had the pleasure of attending—I hope it will not be the last. I also wish to express regret that Commissioner A. H. Jones, the Illinois Pure Food Commissioner, is not able to meet with you and address you this afternoon. He has been out of the city some little time on business connected with the Commission and returned this noon. I expected to see him this afternoon and invite him to come this evening, and perhaps he will be here. The members of the Chicago Association know how much interest he takes in the question of pure food, especially in regard to adulteration of honey. Before he had accepted the duties of the office he came before the Chicago Association and outlined to them his policy in regard to preventing this fraud and deception in the sale of honey, and that policy he has continued, and to-day there are but very few adulterated goods upon this market. Of course this is not the season for honey, but we expect to make a more vigorous crusade in the winter months when honey becomes a prominent product on the market. Adulteration has had a long and prosperous reign in this State. Mr. Moore referred to the work of the Chicago Association in trying to prevent the sale of fraudulent honey before the commission was started. We did not succeed in making any convictions. However, we did succeed in purifying the market to a great extent of the adulterated goods in Chicago, but not so in the small cities of the State. About six months ago, I think it was, we got a large number of samples from Aurora and from Rockford in this State, and of the samples in Aurora, I believe, almost half of them proved to be adulterated. In Rockford the situation was not quite so bad. This was before the law went into effect, which was July 1st. As I said, we have not done much in the line of honey since July 1st. I have examined a few samples, and what I examined were pure honey. Heretofore the manufacturers of adulterated honey that has been put upon the market in the past few years have come to me and said that they will hereafter comply with the pure-food laws and sell as the State requires, with the name "ADULTERATED HONEY" in large type on the front of the label. When the situation comes to that, it will not be so bad for the bee-keepers. I brought along a couple of samples of goods that came in, within the last week, which shows to you another phase of adulteration. The goods are not honey, don't pretend exactly to be honey, but they use the word honey in describing the adulteration; the word honey is another name, and the manufacturers of

these goods are only too willing to use that to assist them in selling the goods. One of them is called, I believe, "Malt Honey." There is no honey in the preparation at all. There is another name for it; they don't care to call it by that name; they would rather call it by the name of "honey." That company has been asked to leave off the name honey from their goods. The other sample is a syrup that is labeled "Honey Syrup." There is no honey in that sample, either, and that was taken by one of our regular inspectors out over the State, and since the law went into effect, the word "Honey" has been scratcht off. We hope to prevent the use of the word honey altogether on the goods which do not contain honey, unless there is some honey in the preparation, or unless the word "Adulterated" accompanies the word honey. Of course, they can use the word honey if the word "adulterated" appears in large letters equally as prominent.

Mr. Green—I have seen honey on the market which was labeled "Imitation Honey" with the word "imitation" very small type. Does that comply with the law?

Prof. Eaton—No, sir; that does not comply with the law. The law requires that the word "adulterated" shall be on in large and conspicuous type. I have noticed that myself, but the company that has been putting out the most of it in this State intends to use the word adulterated. This [indicating] shows you the way it should not be, but it gives you an idea of the way the law requires it to be labeled "Adulterated Honey." You will notice they put this [indicating] in red letters on a red background as they don't show up as well as they ought to. Hereafter they have agreed to put on better letters. This is the label the gentleman referred to, probably, where the word "imitation" occurs in small letters on one corner and the word "Honey" in prominent letters; that is illegal. It will be hard to prevent, I presume, the use of the word honey in the way I have spoken of, because it will be impossible to apply the same principle to other goods. For instance, selling coffee, where the word "coffee" is used on the can; that word is so commonly used and there is so little fraud in it, perhaps there is no great objection to its use. A little more objectionable, perhaps, are the words "Fruit Cocoa" which some of them are using. I am very much obliged to you for your kindness. [Applause.]

Mr. Abbott—I want to call attention to the statement on the label. I want these bee-keepers to see how people trade on their reputation, and the cheek and gall of it. This reads: "This preparation is free from the deleterious properties of this and similar sweets,"—free from the deleterious properties, it says, of honey. I wish some of you would tell us what the deleterious properties of honey are. Think of a firm sending out an article like that and saying it is free from the deleterious properties of honey! If there is anything on God's earth that honey would hurt, I would like to see the thing.

Pres. Root—it seems to me the world is moving when the time comes in the State of Illinois, and perhaps in Chicago, that they have come to the point they are scratching out the word "honey" when it is obviously on a can of bogus stuff. We are making progress, whether the National Bee-Keepers' Association has anything to do with it; it may have had some little influence.

Prof. Eaton—it had a good deal.

Pres. Root—it is encouraging to think we have done a good deal. I would like to have that thing photographed, that word "honey" being crossed out, compelling them to sell goods under their own names. The committee on resolutions will now report.

REPORT OF THE COMMITTEE ON RESOLUTIONS.

Resolved, That this Association urge upon the Congress of the United States the importance of enacting into a law the House Bill known as the Brosius Pure Food Bill; that we would impress upon the individual bee-keepers of the United States the importance of addressing a communication to their Senators and Representatives, asking them to give their support to this bill.

Resolved, That the thanks of this Association are due, and are hereby heartily tendered, to the Chicago Bee-Keepers' Association for its zealous and successful efforts to furnish us accommodations and music for the session of our convention.

Resolved, That the president appoint a committee of three on legislation, looking to the securing of uniform laws thruout the honey-producing States, touching such matters as are of interest to bee-keepers, such as the eradication and prevention of contagious diseases of bees, and

the prohibition and punishment of adulteration of honey, and the injurious spraying of bloom visited by bees.

OREL L. HERSHISER,
EMERSON T. ABBOTT, } Committee.
R. L. TAYLOR,

The resolutions were adopted unanimously.

Mr. York—I would like to move that this body extend an invitation to Commissioner Jones of the Pure Food Commission to attend our session to-night, and Mr. Moore be delegated to notify him, and come with him.

The motion was unanimously carried.

Mr. Burnett—I understand a communication came from Dr. Miller, explaining that his absence from this convention is caused by his sickness, and death in the family. I move you a telegram be sent acknowledging his letter, and sending the regrets of this convention and the hope for his speedy recovery.

The motion was carried unanimously.

Mr. Benton—I want to bring before this body a question which will perhaps require the president to step down from the chair a moment, and may I ask Dr. Mason to take it? He ought to have done so last night. I proposed last evening a vote of thanks for him, for what he has done in providing such fine stereopticon views and also his brother, Huber Root, who also assisted him. Mr. Root was so modest last night he would not put it, and Dr. Mason was so deaf he could not hear, so I now move that the thanks of this Association be tendered the President. Ernest Root, and his brother, Huber Root, for the splendid entertainment they have furnished us in showing the stereopticon views that we have had.

The motion was seconded and unanimously adopted.

Dr. Mason—Mr. President, I am a little bit slow on resolution matters, but I want to have the Committee on Resolutions put in one thanking the Chicago Association for their splendid effort in the direction of doing away with the adulteration of honey in Chicago. Some of us know they have been in dead earnest and thoroly at work in this respect, and I offer that as a resolution, to go with the others.

Pres. Root—Have you one to offer now?

Dr. Mason—Yes.

Resolved, That this Association thank the Chicago Bee-Keepers' Association for the splendid effort it has made and congratulate it on the splendid success it has met with in fighting the adulteration of honey in Chicago.

The resolution was adopted unanimously.

(Continued next week.)

Double vs. Single Walled Hives—A Comparison.

BY J. M. RANKIN.

THE question of double and single walled hives has been discussed pro and con for many years, and there have been strong arguments on both sides. To determine for my own satisfaction the value of protection from the direct rays of the sun during the honey-flow, the following observation was made:

July 7, 1900, five 8-frame dovetailed chaff-hives and five 8-frame single-walled dovetailed hives were watcht. The entrances on all the hives were 7x12 inches and all were fitted with one super each. The single-walled hives were fitted with a flat board cover, while the chaff-hives were covered by a telescope cover having a ventilator in each end and an air space of about 2½ inches all around the super. There was no noticeable difference in the strength of the colonies. All were equally exposed to the sun and all hives were painted white.

In the morning the bees were working freely in all the supers, and no difference could be detected.

At 9 o'clock the thermometer registered 89 degrees Fahr., in the sun, and the bees were all working the same as earlier.

At 10 o'clock the mercury had reached 94 degrees and the bees were still working lively.

At 11 it had warmed up to 99 degrees and the bees were beginning to cluster around the entrances of the single-walled hives, but were still working in the supers.

At 12 o'clock the column of mercury stood at 110 degrees and the bees were beginning to cluster a little around the entrances of the chaff-hives, and had formed a cluster of nearly four quarts on the front of each single-walled hive. No difference could be seen in the supers of the chaff-hives from their appearance when first opened in the morning. Those on the single-walled hives, however, were comparatively empty.

At 1 o'clock the thermometer registered 111 degrees, the highest for the day, and the conditions of the inside of the hives were practically the same as an hour before. There were a few bees above the entrances of the chaff-hives, while the whole front of each of the single-walled hives was covered with bees. The conditions remained the same until toward evening, and no more work was done in the sections on the single-walled hives that day, while the bees in the chaff-hives continued to store honey in the surplus cases all the afternoon.

Altho one experiment will never absolutely prove anything, it would seem that if hives containing bees *must* stand in the sun, it would be a paying investment to see that they are in some way protected from its direct rays.

No. 3—Extracted-Honey Production.

About Getting Stores in Proper Shape For Good Wintering—Brood in Extracting-Combs a Help at the Beginning of the Flow—Manipulating Extracting-Chambers to Discourage Swarming, Etc.

BY R. C. AIKIN.

IN the previous article was discussed the size of hive and effect of conditions upon the strength of the colony and swarming. We learned that a larger brood-chamber was necessary for an extracted colony than for section honey, or, in case the same hive was used, more care and feeding for winter and spring. I showed you that some seasons and localities would change the conditions, and I will further illustrate. Suppose the flow closed in June or July, and you have taken off the surplus combs, shutting down to the brood-chamber. If so, and there is a little honey gathered—sufficient to stock the brood-chamber—your colony gets in condition for winter; but if the extracting-combs are left on till all late honey is gathered, then you may still expect the honey to be almost all in the super, if the colony is strong. A weak colony would store in brood-combs more. Also the size of the brood-chamber makes considerable difference in some things, and as well more or less free communication between brood and super.

Suppose you use an s-frame hive, and the extracting-combs are all worker; after the main flow is over when you extract, a very good plan is to take one extracting-chamber and place it under the brood-chamber. You may ask why under, arguing that if on top it will catch the honey if any comes, and saves lifting the brood-chamber. You are right so far as that applies, but you stop too soon. Place the extra on *top* after the main flow is over, and if there are enough bees they will occupy the extra, and if the weather is warm and some honey comes in, they will be after putting it into the extra. More than this, if there be a vigorous queen, and especially a young one recently begun laying, together with a light flow and warm weather, not only will the little coming from the fields be stored above, but other previously stored below will be moved up to allow the queen to lay freely. Remember that strength of colony, age of queen, temperature, nectar coming in, etc., intensify or diminish the storing above.

But here is another trouble with that extra on top instead of under: Leave your colony thus to go into winter, and before, or by the early spring, at most, the colony shifts upward into the top chamber. Once the cluster is established above, should a siege of cold come on so that the bees can not go *downward* for honey, your colony would perish by starvation. I know this by actual experience. If the extracting-combs are to be given when the flow is probably over, put them beneath. So arranged, the honey that may be stored later is crowded in close above the brood, and thus the stores are made *more* instead of less compact. The good wintering of a colony is very materially aided by a very compact condition of stores, and the stores very close

to the cluster. In extreme cold there ought to be honey within or very close above the cluster. Placing the extra under gives room for the colony to cluster down as much as they please, and they will move downward only just enough to lay the honey in above the brood.

But what about getting brood in the extra if under? Well, unless put there very early in the fall it is not likely any brood will be put in it, but if there should be it will be out before winter, and in the spring none will be put there until the colony becomes quite strong. But what if there is some brood in the extracting-combs just before the flow? It is one of the best things that could happen. Rearrange the hive by putting the brood-chamber again below, then on it a queen-excluder, and the extra with its brood on top. This will cause the colony to occupy the entire hive, and being stretched so are less likely to get the swarming-fever. That brood—even tho' but a little—in the extra, causes the storage of whatever honey comes in *from the very start* to be put in the extra, thus the queen has the brood-chamber to lay as much as she pleases. As soon as storing has well-nigh filled the extra, lift it and place a fresh chamber between it and the brood, and you continue to get the honey in the extra, leaving the queen full sway below. This will almost extinguish swarming in most seasons. It will also leave the colony again without winter stores unless the extra is again put beneath, or a late flow fills up after the extra is off.

I believe there is no better way to keep extras over winter and spring than by this method of placing them *under* the colony. It makes plenty of room below that the dead may fall away from the cluster; it protects the combs, and it also protects the colony against robber-bees. Of course I am speaking of outdoor wintering; if bees are celled they do not need so much room, nor is it so imperative that stores may be in very close proximity to the cluster, tho' I am sure that for *best* results stores should be very compact and close to bees all the time, both indoors and outside.

This kind of management anticipates only worker-comb in the extracting-chambers, at least in such as are put beneath the brood-chambers. A drone-comb there in late fall or winter, even in early spring, makes no difference as it would not be used; the time trouble would come would be in the last two or three weeks just before the summer flow. The extras may be put on top when the colony becomes strong enough to desire and use drone-comb, using an excluder between; but the objection to this is that there is so much extra care needed. It would be so much more simple, and a great saving of care and time, if every colony can be left as they are with their two-story hives until the flow is just on, when one job can be made of the entire yard, in rearranging hives. There is also this in favor of all remaining as they are till the flow is on—the operation of making the shift, rearranging and readjusting, so changes the colony that if preparations for swarming have been begun they would be discontinued. Every colony should be inspected to know if swarming is already anticipated, and cells cut out from those that have been.

I will add here, parenthetically, that if any queen is failing—and weakly ones will (many of them) be at it about this time—you will discover it. If there has not been enough nectar coming in to encourage to swarming, the colonies that have cells at this time, just at the opening of the early summer flow, are preparing to supersede. If the number of cells built run from two to five or six, it is a strong indication of supersede, but if the colony is of good strength it will be almost sure to swarm. Remembering this, you can well understand that much less swarming young and vigorous queens there will be than less swarming. A colony having a vigorous queen, stores normal, and room and other conditions to make it comfortable and easy, will have little tendency to swarm until the season for swarming with its encouraging conditions arrives; but aged or feeble queens may be expected to swarm under quite less favorable conditions, and earlier and later in the season.

I would not think of producing extracted honey without queen-excluders—they are necessary to confine the queen lest there be brood in the extras when not wanted there. A little brood just before the flow begins—say a week or a little more, that it be all sealed—serves the purpose of drawing the colony up to work there, yet does not interfere about extracting. An extra having brood in it when ready to come off for extracting, is much harder to get the bees out of.

It is well to give special attention to this matter of having the stores in close, compact shape for winter, especially in outdoor wintering; it makes a colony winter more safely, and build up better in spring—more safely because stores

are easy of access, and because if brood is closely bound with honey some of that honey will be moved to get it out of the way of the brood-nest, thus better feeding of queen and brood results, that would not otherwise be obtained except by a flow of nectar or by feeding.

If the foregoing management be applied in an intelligent and scientific manner there can be no doubt of good results. And the more one expects to practice the let-alone plan in the spring and early summer, the greater the necessity of the better preparation and obtaining of the conditions relating to stores and strength of colony for winter.

Larimer Co., Colo.

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

FINDING A QUEEN BY FANNING BEES.

Yes, sir, I guess McNeal has a bright, new idea for us. It is according to the probabilities; and if he has tested the matter and found it correct it is worth while for us to test it too. If Queen Victoria was at your house, and you had a movable mechanical arrangement for cooling off things in sultry weather, the mechanism would be run right straight to the room she was in. So first look at the fanning bees outside the hive when you go for a queen in fanning weather. Page 792.

PROPOLIS ON FLOORS AND BOOTS.

That parasite, or incubus, or stick-tight-ibus, on the bee-man's sole—who has not worried his brain more or less for some scheme of relief? Propolis scraped off must needs fly some place (inclines to fly *every* place) and when a body steps he has annexed a lot of it—annexed it on constitution-follows-the-flag principles, too. Mr. Wilcox, page 793, seems to think that down in a cool cellar, which has moist sand only for floor, he can tramp around on propolis scrapings and not have them follow him off. Don't more than half believe he can do it as a regular thing—may be he can. Those of you who can rub in a dram of enthusiasm and a few scruples of faith-cure into the ointment may try it—remedy without something if you succeed. I scrape sitting, hold feet still, keep a broom in reach, and sweep me a path before rising. How is it, brethren? Which way is orthodoxy, and which way is heterodoxy? and who will come with a better-ortho-doxy?

WIRE-RINGING THE QUEEN.

As to capturing the queen, the wire ring to surround her with suddenly, and lift her up with when she steps on it, will be new to many of us. Quite a number of trials we may need before fully deciding about the exact value of it; but it may be that we shall decide that it is a *very* great help in that line of work. The idea is capable of modifications; and it may be that it will yet be improved quite a bit from the way McNeal has it. Page 792.

CRUDE PROPOLIS AS A MARKETABLE ARTICLE.

I think I should look out for a trap, or a snap, or a rap of some kind, if a man wanted to buy crude propolis of me for 50 cents a pound. Price much above the cost of obtaining it, and rather out of proportion to the cost of similar articles—or should I post myself about the cost of varnish-resins before saying that? Anyhow, if a man came around and wanted to buy the waste dish-water of your kitchen at 5 cents a gallon, you'd let him have it; but if he proposed to pay 25 cents a gallon you would postpone things until you could form some opinion as to what the fellow was really up to. It wouldn't be easy for any one apiary to furnish great amounts of propolis; but section scrapings, to the amount of quite a few pounds, could be furnished *cheaper than not*. Costs more to waste it than it would to save it—it has such a won't-be-peaceably-wasted disposition. Those of us who use the wide frames to hold secretions can get a good few pounds any old time (not in the honey season) by scraping our frames. Page 790.

TWO BAD SLIPS OF THE PROOF READER.

Seems to me the proof-reader must have been making New Year's calls shortly before he read the last After-

thought. Butter is *sold*, not "said," and the anti-progress monster was *fought*, not "bought." Nobody not already in his claws would ever buy him. Page 11.

A BEE AND FRUIT PAMPHLET NEEDED.

A little pamphlet which is not yet in existence was evidently what that legal man on page 803 needed—"The Habits of Bees in Regard to Fruit Impartially Stated by Authority." It should be gotten out by some government entomologist, and be reviewed and endorsed by Uncle Sam's head fruit-man. Then lawyers (and courts, too, to some extent) would accept it. You see, we'unas are apt to state things pretty strongly on our own side and if we didn't we would be suspected of doing so so sharply that our pamphlet wouldn't count much.

THE ITALIAN BEE "NOT THE WHOLE THING."

In Mr. Dadant's letter, on page 806, I was particularly interested to see that Swiss bee-keepers (as well as many of the British) do not give the preference to the Italian bee. By and by the whole actual fact about races of bees will get to the surface; and it is quite possible that the best bee for one locality will not be the best bee for another locality. Bees that could be depended upon always to crowd the queen with honey, and check her laying in times of plenty, would be very desirable where the harvest is all in one short flow; but where moderate flows are scattered all thru the season such bees would get so weak as to be worthless. And the Italian is the worst of a queen-crowder that we have. I believe.

Mr. J. B. Hall, of Canada.

The man whose portrait we are permitted to present on the next page, is one of Canada's very brightest and best bee-keepers. We had the great pleasure of meeting Mr. Hall at the convention of the National Bee-Keepers' Association held in Toronto, Ont., in September, 1895—the last convention which Father Langstroth attended.

Editor H. E. Hill, of the American Bee-Keeper, was at one time an apiarian pupil of Mr. Hall, and to this day takes much pride in that fact, as well he may. Recently Mr. Hill had this to say of his former teacher, in his paper which he so ably edits:

We have pleasure in presenting in this number a most excellent portrait of Mr. J. B. Hall, of Ontario, one of the Dominion's acknowledged leaders in things apicultural.

While Mr. Hall is a very earnest and popular association worker, it is to be regretted that, for some years past, all persuasion and force, in their oft-repeated applications, have proven inadequate to the purpose of eliciting from his pen contributions to the bee-keeping press. This is the more to be deplored when we consider the fact that Mr. Hall's pen productions have a style at once interesting and instructive, peculiarly their own. A more methodical and painstaking bee-master than Mr. Hall can not be found—nor a more successful one. Too many futile efforts have stealthily been made to remove the "bushel" in which so much "light" is confined, to leave any hope for the future in that direction; but, were it not for the profound respect which we feel for this esteemed instructor of our youth, we should not hesitate to suggest the trial of a quicker method of removing it. This might, however, prove equally ineffectual, and we shall neither try nor recommend the kicking plan.

Mr. Hall is a producer of honey, and, being such, he says he has nothing but honey to sell. His favorite bee for the production of comb-honey is an Italian-Carniolan cross, of which he has an excellent strain. He is the originator of the thick top-bar and of the wood-zinc excluder; the too modest to assert his right to the honor.

In the conduct of his business, Mr. Hall's operations

are governed by attendant conditions and their immediate requirements, from the standpoint of independent reason, and not according to any set of stereotyped rules, as is too frequently the case with bee-keepers. He is, obviously, a case of "the right man in the right place;" and there is ample evidence on every side, of the wisdom of his choice in adopting apiculture as his profession.

At the present time a week seldom passes in which we do not have occasion to recall some of the advice and admonitions given with his characteristic earnestness and kindly manner, 15 years ago, when he labored to eliminate the erroneous ideas which we had previously acquired, and to establish in their stead a clear understanding of what they appeared to be a most obscure subject.

That our younger readers may fully appreciate the picture, we have pleasure in reproducing a few paragraphs from the Canadian Bee Journal's report of the meeting of the Ontario Bee-Keepers' Association, held at Toronto, in December, 1899. Mr. McKnight's motion was evidently a spontaneous outgrowth of the same sense of obligation and high esteem to which every man is subject who has been intimately associated with the gentleman whom he sought to honor. It is a sense of obligation and esteem which, as we know by actual experience, constantly increases by long and very intimate association:

"Mr. McKnight—There is a little matter which I would like to bring up. We have a gentleman with us during this convention who is here only by the solicitation of a great many members. This Association has been a great success right from the first until now, and that is something creditable. There have been men who have done more than Mr. J. B. Hall has for this Association in a purely business way; but I want to tell you there is not a man belonging to this Association now, or ever did belong, who has made its meetings so interesting and practical as our friend Hall. [Applause.] He has been the life and soul of our Association meetings for the last 19 years. Like myself, the world is largely behind him; he has not many years to be here, and I think it would be a graceful thing to do anything in our power to show our appreciation of the value of his services. Altho he does not say very much outside of this Association, Mr. J. B. Hall is known all over the continent of America. I would like to move that this Association make J. B. Hall a life member—that is all. [Loud applause.] I would like, if it were in my power, to confer some higher honor upon him, but I know he does not want it; and I am not sure whether he would appreciate even this; but I know it is our duty to show Mr. Hall some mark of the appreciation of the valuable services he has rendered to the bee-keeping interests of this Province. I hope this will not be made a precedent; it would be very little honor if all the old men were associated with him; I would like to see Mr. J. B. Hall the one and only life member of this Association during my lifetime.

"Mr. Brown—I have very much pleasure in seconding Mr. McKnight's motion. I can indorse every word he has said with reference to Mr. Hall.

"The motion was carried by a rising vote, and the singing of 'He's a Jolly Good Fellow,' after which Mr. Hall briefly and suitably replied."

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Queen-Rearing is a very interesting part of bee-keeping. Mr. Doolittle's book tells practically all about the subject. See the offer we make on page 30 of last number.

Mr. J. B. Hall, of Ontario, Canada.

—From American Bee-Keeper.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

[The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.]

A Beginner's Questions.

This is my first year with bees, and I would like to know how to keep them successfully. I want to increase as well as to work for comb honey.

We have cold weather and snow usually from Dec. 15th to March 15th. It has been from 5 to 10 degrees below zero here for 10 days, and lots of snow on the ground.

1. What kind of hives and supers should I use for best results?

2. I took the third frame of brood from an 8-frame dovetailed hive last summer, and put it into a hive with foundation, in order to get the swarm to stay, as well as to strengthen them. The colony was strong at the time with bees and honey. On examining, before I put them into the cellar, I was surprised to find how few there were dead, and I now have a colony with eight brood-frames of honey.

On removing the frame of brood, I brushed all the bees from it. What caused them to dwindle and die?

3. Can I feed those combs of honey to two weak colonies I have, or should I give them sugar syrup? I am wintering 20 colonies in frame and box hives.

4. I had five colonies last spring that gave me 20 to 30 pounds of surplus comb honey each. The swarms gave me no surplus. I put them on new stands with one frame of brood and seven frames of foundation 3 inches wide. What could I have done to make them do any better?

NEW BRUNSWICK.

ANSWERS.—1. The kind of frame hive you already have is the one to continue, unless there is some good reason for making a change, for it is a very troublesome thing to have two kinds of hives in the same apiary, especially if they have frames of different sizes. The size of frame most generally in use is probably as good as any, measuring 17½x9½, outside measure. This is the frame used in the dovetailed or Langstroth hive.

2. Very likely they were queenless.

3. It will be all right to use the combs of honey, unless the bees were diseased, which is not likely.

4. You got all your honey from the old colonies, and none from the swarms. It may be that you would have had more honey if you had depended more on the swarms by managing in this way: When the swarm issues, put it on the old stand, setting the old hive close beside it. A week later remove the old hive to a new location. That will throw the whole field-force into the swarm, and altho you may get nothing from the old colony, you will have a strong force in the swarm, and your total yield may be greater.

What Killed the Bees?—Other Questions.

The season of 1900 opened the best in many years, with a big flow from fruit-bloom, mostly from plum and wild cherry, the scales showing a gain of four to six pounds per day. Then the great drouth commenced, which lasted until Aug. 4th. It was too dry for basswood to yield nectar. From the above date until September there was almost a daily rain. The stores from the spring-flow were about all gone, and it looked as if every colony would have to be fed, or starve. The rain brought an immense growth of weeds on the wheat stubble, and with a few fair days the bees filled their hives with the most villainous honey you ever saw, almost black, and the flavor was worse than anything I ever met with before. It was from what is called wild buckwheat—a vine that has a seed shaped like buckwheat. A few cold, rainy days followed, when the bees commenced throwing out dead larvae and young bees. Examining, I found frames of brood being uncapped, with not an egg or young bee alive. This was the case with every colony (about 80), and there was not another bee reared, to the best of my knowledge, and I examined them frequently.

1. Now, the question is, what killed them?

2. Will they rear brood in the spring on such stores?

3. Will it be best to take the honey away and feed as soon as taken from the cellar? They seem to be wintering all right, with no unusual number dying.

CENTRAL MINNESOTA.

ANSWERS.—1. I don't know. It looks as tho that villainous black imitation of honey killed them. Yet from what you say they must have been living on the same stuff since, and it does not hurt them. It is just possible that they got something poisonous that killed them, and none of it is now in the hives.

2. As they are wintering well upon it, it is quite likely they will rear brood with it next spring.

3. Keep a close watch in spring, and if everything goes straight, and brood appears healthy, let it be; but if the brood dies, or there is no brood, then change the stores.

Spring Feeding—Two Apiaries or One?

1. Do you know of any objection to the following plan of feeding and strengthening a colony in the spring? Would bees object to the partial division of their home when in two hives? If not, would they be less likely to swarm, when on 16 Langstroth frames?

Start feeding an 8-frame colony early in the spring, and before the queen gets crowded put them in a 10-frame hive. Go on feeding, and then transfer them to two 8-frame hives set close together, with the adjacent sides perforated every few inches, and with a bee-way top and bot-

tom. Go on feeding gently until a week before the honey-flow, and then put on two supers, side by side.

2. Will bees refrain from carrying up syrup fed to them, so long as the queen is not crowded?

3. Do you think there would be any advantage, so far as yield of honey is concerned, in dividing an apiary of 140 colonies, spring count, when the out-apiary is to be only ¼ mile distant from the home-apiary, assuming, of course, equal conditions all around as to bloom? MINN.

ANSWERS.—1. The probability is that the queen would not go readily from one hive to the other, when you had the two hives side by side with holes for passageways, and if she did go from one to the other, there would be some likelihood of the bees starting queen-cells in the one she had left.

Instead of first changing from the 8-frame hive to a 10-frame, and then to two 8-frame hives side by side, it would be much simpler, and probably better, to start at once with the two 8-frame hives, putting one hive over the other. As soon as you think the bees are in danger of being crowded with only eight frames, put the second story under the first. Even if this is done before the bees are at all crowded, it will do no hurt. The heat of the hive rises, and an empty hive below would not cool off the brood-nest as it would with the empty hive above or at the side. Then when the bees became crowded above they could work down into the lower story; or, if you thought they were too lazy about it you could put a frame of brood from the upper story in the lower story. But when it comes time to put on supers, I have always found it better to take away one story, crowding with brood the story left.

2. Yes, the bees will store in the brood-combs anything fed to them, so long as there is plenty of room there. But it is not wise to crowd the brood-nest at any time, for there is a possibility that the combs may fill up so rapidly with brood that the bees will feel obliged to empty some of the cells in the brood-combs of their stores, carrying the same up into the super, altho when the stores were given there may have been abundance of room in the brood-combs.

3. Most surely, in any ordinary location. The only exception would be in some location so remarkably rich in resources that 140 colonies could get all they could gather without going farther than ¼ of a mile from home.

Using Extracted Honey-Dew Profitably.

How can extracted honey-dew be used in the apiary to good profit and advantage? What other uses can there be made of it?

KANSAS CITY.

ANSWER.—It can be fed to good advantage in the spring to be worked up into brood. It may also be sold for manufacturing purposes.

Getting Extra Extracting-Combs.

Being short of extracting-combs, I am thinking of filling the supers next spring with combs, and the frames with starters, half and half, alternately. How would it do?

I extracted my fall aster honey in November, and got about 40 pounds for the colony, which makes about 70 pounds for the year—about an average with us here. I winter my bees outdoors, of course, and up to this time they have had a good flight every day, if not raining.

SOUTH CAROLINA.

ANSWER.—If I understand you rightly, there will be a fully-drawn comb, then a frame with a starter perhaps an inch deep, then a drawn comb, then a starter, and so on. An objection to this, especially if the harvest is at first a little slow, is that the bees will draw out deeper the cells of the fully-initiated combs, and will make the newly built combs very thin. It may be better to have all the drawn combs together on one side, and all the starters together on the other side. Then your combs will be more uniform in thickness. If the extracting-combs are of the same size as the brood-combs, you might like the plan of having the new combs built in the brood-nest instead of in the super. In that case you can alternate the frames, for when used for brood there will not be the same danger of having the combs unequal in thickness. Moreover, if you prefer worker-combs, you will have less drone-comb built in the brood-nest than in the super.

The Premiums offered this week are well worth waiting for. Look at them.

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & CO.

118 Michigan St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

IMPORTANT NOTICES:

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, Six a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec 00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts—We do not send a receipt for money sent as to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and fully credited.

Advertising Rates will be given upon application.

Reformed Spelling.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

Maule's (35 new things for 1901) Seed Catalogue

You should, by all means, have this most modern catalogue of modern things. It is original and overflowing with good things in vegetable, farm and flower seeds, flowering plants, fruits, bulbs, etc. It contains 35 novelties in vegetables and flowers never offered before, has 146 large pages, seven handsome colored plates and hundreds of illustrations. It gives practical, up-to-date cultural directions and offers many cash prizes. The first edition alone costs over \$400, so while we send it free all customers, we must ask others to send 10 cents for it, which amount they may deduct from their first order. You will make a mistake if you do not write to-day for this the Novelty Seed Book of the year. Address, WM. HENRY MAULE, Philadelphia.

3D4 Please mention the Bee Journal.

HAMMOND'S Mammoth Tomato.

Most perfect seed and best in the world. Hammond's Mammoth made a specimen last year weighing 1 1/2 lbs. Largest tomato that grows. Hammond's Large-Hearted Tomato Plant has extraordinary others in earliness. Hammond's Great Tail Tree, Hammond's Heart Tree, Hammond's Golden Beauty, and Hammond's Peppercorn are novelties of wonderful merit. Handsome illustrated catalog of tomatoes, given in progress for 1901 and all leading varieties of Potatoes, Field, Flower and Vegetable Seeds mailed FREE on request.

GENERAL ITEMS

A Good Report For 1900.

I started the season of 1900 with 62 colonies of bees, increasing to 115 colonies, and got 4500 pounds of nice honey, all of which I sold in the home market. One-third of it was comb-honey, which I sold for 10 cents per pound, and the extracted at 8 1/2 cents.

LON ROSSON.

Ellis Co., Tex., Dec. 27.

Bees Did Fairly Well.

My bees did fairly well the past season, averaging 50 pounds per colony, but it was very dry all summer, and one of my neighbors did not get any honey at all. There are very few beekeepers around here, and our bees have a large range. They are wintering finely so far. Dec. 23d and 24th they had a good flight and look healthy and strong in numbers.

I am going to try the fences and plain sections next season as I believe they are an improvement.

J. WARREN SHERMAN.

Suffolk Co., N. Y., Dec. 29.

Report For the Season of 1900.

We have had another poor honey season in Texas, altho there was considerably more honey produced than in 1899. We commenced the season with 500 colonies, had but little increase, and harvested 21,000 pounds of honey, divided as follows: Extracted 11,900 pounds; bulk comb, 7,840 pounds; section honey, 1,464 pounds. We have had abundant fall rains, and vegetation is up; we therefore expect a good crop for 1901.

A few days ago we sent our renewal to the American Bee Journal, which we can not do without.

O. P. HYDE & SON.

Williamson Co., Tex., Jan. 1.

Bumble-Bees in Winter.

On page 809 (1900) a beginner asks, "Where do bumble-bees winter?" As I am pleased with the question, and would like to have some naturalist tell us all about it.

In Canada we have several kinds of bumble-bees, some very small and others all the way to very large. They

are variously and beautifully marked with pleasing colors. The smallest of all are the rarest, but their nests are the richest in honey. The medium sizes winter generally in the woods under old logs, where there is a large accumulation of old leaves. The smallest and largest may winter in the same fashion, but I don't know about that. I have often wondered if it could be that they migrate to the South like the birds, and spend a season there, and return North the following spring. Only the queens live thru the winter. I have handled a good deal of wood, logs, rails, and timber in my day, but never found any of the smallest or the largest kinds in winter. Who will tell us all about it, in the columns of the "Old Reliable," just by way of diversion and information?

Ontario, Canada. S. T. PETTIT.

Bees Didn't Do Well.

I have 20 colonies of bees, but they didn't do well last season. We hope next season will be a better one for bee-keepers.

I appreciate the Bee Journal very much, and can't very well get along without it. H. C. ROBERTS.

Lawrence Co., Ohio, Jan. 8.

Bees Wintering Nicely.

Bees are wintering nicely in the cellar, but no snow on the ground is hard on the clover. N. STAININGER.

Cedar Co., Iowa, Dec. 12, 1900.

No Honey Last Season.

I have 29 colonies of bees in good condition on the summer stands, but I got no honey the past season. There

were plenty of blossoms, and I never saw bees do better on fruit-bloom.

I can not do without the American Bee Journal as long as I keep bees, which will probably not be many years more, as I am 71 years old.

S. HARPST.

Mercer Co., Pa., Dec. 31.

Prospect Fair For Next Season.

The honey crop last season was an entire failure in this part of Ohio.

Bees are enjoying a flight today. Mine appear to be all right, tho I had to feed for winter.

White clover is plentiful and the prospect is fair for the coming season.
G. C. ALLINGER.

Marion Co., Ohio, Jan. 10.

How to Sell Candied Honey.

Years ago I came to the conclusion that the proper way to dispose of extracted honey was to sell it in tin packages in the candied form, and I began putting up our honey for the winter trade in raised-cover tin pails, and for my trouble I met lots of opposition, but I determined that the battle must be fought along that line. I first had to overcome the prejudice to candied honey by guaranteeing my honey to be strictly pure, and that it would candy in cold weather. The next trouble was that the packages were too dear for my customers, and I began using 3-pound tin fruit-cans and sealing the lids with wax (grafting wax is best). I get 23 cents per can, or \$2.75 per dozen; this is for fall honey, mostly touch-me-not. I buy the cans by the gross, and stick on them a neat label. For the summer trade I use the one-pound glass jars to a small extent. I get \$1.32 per dozen for glass jars.

My crop of honey was 1,675 pounds of extracted honey from 63 colonies.

C. A. BUNCH.

Marshall Co., Ind., Dec. 28.

Wintering First-Rate.

There was not a blossom of white clover or Linden the past season, and my bees did very little. They are wintering first-rate.

The thermometer is 8 degrees above zero this morning, and weather clear. We have had but little snow, and fine weather.
H. MESSER.

Green Co., Pa., Jan. 4.

Not Much Surplus Honey—Foul Brood.

The bees did not store much surplus last season. They did fine in the spring during maple, elm, box-elder and locust bloom, and also during fruit-bloom of all kinds. I expected to get a large amount of honey, but you know how often we are disappointed in our expectations, and I did not get over 25 pounds of surplus honey, all told. Swarming commenced the latter part of April and continued until June 2d. My bees never were in better condition for work, being very strong. I sold 40 colonies the latter part of May to a bee-keeper in this county, and he secured considerable honey.

I have about 50 colonies left, which are in good condition for winter. I winter my bees on the summer stands,

Langstroth on "The Honey-Bee"

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

118 Michigan Street, CHICAGO, ILL.

and they are always packed, summer and winter—"what will keep out the cold will keep out the heat," you know. The covers are sealed down tight, and soft-maple leaves are packed two inches in front of the hives, 4 to 5 inches at the sides and back, and 7 or 8 inches on the top of the cover. The outside cover is $\frac{3}{8}$ to $\frac{1}{2}$ inch thick. All hives have good shingle covers projecting all around the ends and sides. I can put my hand in among the leaves on top of the hive in the coldest weather and it will be quite warm. I have had very little winter loss for a number of years, or since I got rid of foul brood.

I lost hundreds of colonies from foul brood. I bought some bees that had it, and once it got into the apiary I had a time of it. I did not then know what it was, but tried everything to get rid of it, and burned a great many colonies, hives and all. That was about 8 or 9 years ago, and I do not remember when I got rid of it.

Some of the old hives that were in use at that time were piled up, their covers put on after the bees were dead, and were left in the apiary. I cleaned out some of them two or three years ago and put new swarms into them. I boiled some of the frames so as to be on the safe side, and tried a few without boiling, and there was no difference—no signs of foul brood in either case—so I scraped all the old hives and frames and they are now in use. I sent specimens of the foul brood to A. I Root and Dr. Howard. I detested the odor of foul brood, but workt with it until I got rid of it.

D. C. MCLEOD.

Christian Co., Ill., Dec. 29.

Bees Did Poorly.

Bees did poorly in this neighborhood last season, but mine gathered enough for winter and stored an average surplus of 12 pounds per colony, amber extracted, from fall flowers.

May the American Bee Journal long prosper, and if bee-keepers can't afford to send in the dollar we might as well give up trying to keep bees.

S. O. LARSON.

Isanti Co., Minn., Dec. 31.

Report For The Season of 1900.

We run about 250 colonies for comb and extracted honey the past season, and averaged 50 pounds to the colony. We hope to do better in 1901.

We winter our bees on the summer stands with sawdust on top of the frames.

W. J. STEWART.

Utah Co., Utah, Dec. 31.

Aster as a Honey-Plant—Introducing Queens.

The honey-crop in 1900 was about as much of a failure as in 1899, if not worse, but we should be thankful for what little we did get, and hope for better things the coming season.

I began with two colonies, spring count, increased to five, and secured 198 pounds of honey.

I also had charge of an apiary which we began with 23 colonies, spring count, increased to 24, and secured 1,200 pounds of extracted honey, mostly from aster.

Mr. W. W. McNeal certainly gives

the aster a much-deserved good name on page 793 (1900). I would advise "Mississippi," page 783, to try this, as he says he is searching for good honey-plants. It has proven a boon to beekeepers here. It comes into bloom the very last of September, and gives us a fair surplus, besides a force of young bees for winter, and bountiful winter stores. It granulates very quickly, however, especially when extracted; I have known it to granulate solid in 10 days, and when mixed with no other kind of honey it has much the appearance of lard.

Last June I received a tested queen from a noted queen-breeder in the East. She arrived all right, and I put her away until the next morning, as I was very busy at the time. The next morning I destroyed the reigning queen, and as I had so much work on hand I did not take time to separate the new one from her escorts, but pulled back the wire-cloth, exposing about an inch of candy, and set the cage on the top-bars of the hive. Some honey was coming in at the time, but I was also feeding them. I examined the hive 48 hours after the queen was released, but in a day or two when I lookt again there were numerous bunches of queen-cells, but no queen to be seen. J. WILEY MOUNTJOY.

Anderson Co., Ky., Dec. 22.

Bees in Good Condition - Swarming.

Bees went into winter quarters in this locality strong in numbers, and plentiful in stores. Most of them were left on the summer stands until late in November, owing to the mild weather. They stored an average of about 50 pounds per colony of surplus honey, also some colonies stored as high as 100 pounds—I think mine did, spring count.

In my apiary, some years ago, a large swarm issued in June: without making any attempt to cluster they put for the woods, which is but a stone's throw from my apiary. They went slowly, flying around the tops and bodies of the trees they past. I was quite certain they had a tree lookt up in which they

were intending to settle, and, sure enough, after going about 80 rods they settled about 60 or 70 feet from the ground in a pine-tree, which was about 3½ feet in diameter. The next morning I cut down the tree and safely hived the bees. Doesn't this look as tho they had this tree lookt up, and went directly from the hive to the tree?

The "Old Reliable" continues its weekly visits, and is a most welcome guest, freighted with so many good things. Long may it and its editor live to bless the fraternity which they represent.

L. ALLEN.

Clark Co., Wis., Jan. 5.

Bees Light in Stores.

Bees went into winter quarters light in stores, and I may have to feed them in the spring. I am wintering some in the cellar, and some in an open shed facing the south.

My eyesight is poor, and I can hardly see to read the Bee Journal any more, but I still keep some bees, and I don't like to give it up, as I can see to read it a little.

NOAH MILLER.

Iowa Co., Iowa, Jan. 8.

Poor Season for Bees in 1900.

I put 75 colonies of bees into the cellar last winter. One died of starvation, and 4 were queenless. I had 9 first and 3 second swarms, and 5 left the hive before I started to break them up. Some of the new colonies had about one pound of honey when I robbed them, and some of the old ones had very little honey. They had too many bees for so poor a season as the last was.

I took 700 pounds of comb honey from the supers, and have 266 pounds on hand yet.

I put 53 colonies into the cellar on Nov. 25th. The prospects for next season are good, provided we get plenty of snow to cover the clover, which showed up nicely last fall.

WM. DUESCHER.

Brown Co., Wis., Dec. 28.

CONVENTION NOTICES.

Minnesota.—The annual meeting of the Southern Minnesota Bee-Keepers' Association will be held at the court house in Winona, Jan. 23, 24, 1901. A very elaborate program has been arranged. It is intended to secure a chorus of girls to render several musical numbers, and it is expected that the attendance will be very large. Among other good things on the program are the following: Address by Pres. E. B. Huffman; Song, "Hymn of the Bees in the Apple Tree Bloom;" Bee-Keeping as a Source of Pleasure and Profit, by E. B. Huffman; "Reminiscences of Bee-Keeping," by J. Turnbull; "Different Strains of Bees," by F. Oech; "Production of Section Honey," by W. K. Bates; "Keeping Queen Bees," by E. B. Cornell; "Wintering Bees Out-Doors," by Wm. Berthel; "Implements Used in Bee-Keeping," by J. M. Riet; "How to Exhibit Honey," by Frank Yahner; "Bee-Fur," by W. F. Martin; "Marketing Honey," by Peter Oech; "Managing an Apiary," by Phil Gardner; "Dividing Colonies of Bees," by Jas. M. Gates; and "Prevention of Swarming," by T. B. Rand.

Winona, Minn. C. A. GLE, Sec.

Grow Rich, Mr. Farmer.—Every farmer is ambitious to put aside a snug sum for the later years of life, that is just right, but why not grow rich doublequick. You can do it. How? By planting plenty of John A. Salzer's Seed Company's La Crosse, Wis., grown seeds. You see Salzer breeds his seeds up to big fields, as the farmer breeds his cattle to their highest point of merit. The result is, Salzer's seeds sprout, grow, and produce copiously. Many a farmer's granary had to be built larger, and his barns needed additions put on, on account of sowing Salzer's seeds; that's good, prosperous news. Please mention the American Bee Journal when writing.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Dec. 21.—The demand has fallen off very much of late, but prices have not declined to any great degree from those prevailing for the past 60 days, but any pressure to sell would cause a decline. Fancy white comb, 1½¢; 1, 1½¢; amber and travel-stained white, 1½¢; dark and buckwheat, 10¢. Extracted, white, 7½¢; amber, 7½¢; buckwheat and other dark grades, 6¢. Beeswax, 10¢.

R. A. BURNETT & Co.

KANSAS CITY, Dec. 21.—Honey market firm, demand steady. Fancy white comb, 24-section, case, \$3.50 to \$3.75; 12-section case, \$1.90 to \$2.00; amber, case, \$3.00 to \$3.25. Extracted, white, 8¢; supply fair; receipts and demand good. Beeswax, 12½¢. Demand fair.

W. R. CROMWELL PRODUCE CO.

Successors to C. C. Clemens & Co.

BUFFALO, Jan. 4.—Honey market is very quiet and unsatisfactory. The various lots here must be cut sharply to sell. Fair, 15¢; 16¢; fair to good, 10¢; but prices are shaded according to the case. No extracted wanted. Beeswax quiet at 25¢. BATTERSON & Co.

ALBANY, N. Y., Jan. 5.—Fancy white, 17¢; No. 1, 16¢; No. 2, 14¢; mixt, 13¢; 14¢; buck wheat, 12¢; 13¢. Extracted, white, 8¢; mixt, 7¢.

Honey market slow with light stock, but selling at concessions, especially on extracted, which have been holding too high everywhere. H. R. WRIGHT.

BOSTON, Dec. 22.—Fancy No. 1 white in cartons, 17¢; No. 1, 16¢; No. 1, 15¢; 16¢, with a fairly steady demand. Absolutely no call for dark honey this year. Extracted, white, 7½¢; 8¢; light amber, 7½¢. Beeswax, 27¢.

BLAIR & SCOTT & LEE.

CINCINNATI, Jan. 4.—The market for comb honey here is becoming a little bare, although prices are not obtainable. Fancy white comb is 13¢; lower for white, and 7¢ for amber; all extracted is selling slow; amber for 5¢ and higher; fancy white clover brings 8¢. Beeswax, 28¢. C. H. W. WEBER.

NEW YORK, Dec. 22.—Fancy white, 15¢; No. 1 white, 14¢; No. 2 white, 12¢; 13¢; amber, 12¢; buckwheat, 10¢. Extracted in fairly good demand at 7½¢ for white, and 7¢ for amber; off grades and Southern in barrels at 6¢ to 75¢ per gallon, according to quality. Not much demand for extracted buckwheat as yet. Some little selling at 55¢. Beeswax firm at 28¢.

Demand continues good for comb honey; supply fairly good. Extracted in fair demand with enough supply to meet requirements.

HILDRETH & SEGELSEN.

DETROIT, Dec. 22.—Fancy white comb, 15¢; No. 1, 13¢; 14¢; dark and amber, 10¢; 12¢. Extracted, white, 7½¢; 8¢; amber and dark, 6¢. Beeswax, 26¢. M. H. HUNT & SON.

SAN FRANCISCO, Dec. 19.—White comb 13¢; 14¢; amber, 11¢; 12¢; dark, 8¢; 9¢. Extracted, white, 7½¢; 8¢; light amber 6½¢; 7¢; amber, 5½¢. Beeswax, 26¢.

Stocks of all descriptions are light, and values are being as a rule well maintained at the quoted range. Firmness is naturally most pronounced on light amber and water white honey, the latter being in very scanty supply.

HONEY MARKET.—We may have a customer within a short distance of you who wants your honey or beeswax. We are in touch with all the markets; therefore write us regarding your crop, stating quantity, quality, and lowest cash price. References—Either Bank here for any business man in this city.

CHAS. DADANT & SON, Hamilton, Hancock Co., Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a lifetime, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise it tries to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us FIVE NEW SUBSCRIBERS to the Bee Journal (with \$3.00). We will club the Novelty Knife and the Bee Journal for one year, both for \$1.90.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Reformed Spelling.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equip, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

118 Michigan Street, CHICAGO, ILL.

YELLOW OR WHITE

Sweet Clover Seed

Free as a Premium

For Sending us One New Subscriber for a Year.

There has been so much written about both the white and the yellow variety of sweet clover, that we will simply say here that if one of our present regular subscribers will send us \$1 with a new name for this year, we will mail, postpaid, to the one sending the new name and the dollar, either one pound of yellow sweet clover seed, or two pounds of the white sweet clover. This is a good chance to get a start of both kinds of these honey clovers. Better send two new subscribers (with \$2.00) and get the three pounds of seed. Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO, ILL.

BEST

Extracted Honey For Sale

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough the Alfalfa extracted.

BASSWOOD HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

Prices of Either Alfalfa or Basswood Honey:

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are boxt. This is all

ABSOLUTELY PURE BEES' HONEY,

The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:

I've just sampled the honey you sent, and it's prime. Thank you. I feel that I'm something of a heretic, to sell several thousand pounds of honey of my own production and then buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drink, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honeys of more market flavor, according to my taste. C. C. MILLER.

McHenry Co., Ill.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

Bee-Keeping at the Pan-American.

—The busy bee will be in big business at the Pan-American Exposition the coming summer. It has been decided to construct a special building for the proper display of the working colonies of bees and the great variety of bee-keepers' supplies which will constitute this exhibit. It is expected that this will be the most extensive bee-exhibit ever prepared in this or any other part of the world.

The exhibits will be so arranged that the bees may enter their hives from the exterior of the building, and carry on their work undisturbed by visitors, yet in full view thru the glass sides of the hives. As the successful management of an apary requires a knowledge of botany as well as the habits and requirements of the bees themselves, this exhibit will illustrate the operation of an apary, and will show the common honey-producing flora in a way to be understood by all who may be interested. The relation of bees to horticulture and agriculture will be clearly shown, and the many uses of honey illustrated.

Since the invention of the movable-frame hive by Langstroth in 1851, the application of labor-saving, honey-saving, and bee-saving devices has been very interesting and important, as is well known by up-to-date bee-keepers everywhere. It is intended to make the most complete display ever seen of things apian at the Pan-American Exposition.

Amateur Bee-Keepers is the heading of an article by Rambler, in *Gleanings in Bee-Culture*. He contends that to the amateurs the bee-keeping world owes quite a debt. He begins with Sanson, who found a colony of bees in the carcass of a lion. "Some writers going so far as to claim that Sanson invented the movable-frame hive, from the supposition that the bees build the combs to the ribs of the defunct lion; and it was the comb attached to one of these ribs with which he sweetened himself."

Rambler then mentions Virgil, of later time, followed by Huber, and notes in passing that contemporary with him were many German investigators who were amateur bee-keepers.

Then coming across the ocean he finds Langstroth, who was never an extensive bee-keeper, yet it was he who by the invention of the movable frame opened to view the mysteries of the hive, and made it possible for

bee-keeping to become a remunerative business.

After that, again jumping back over the ocean, it was Hruschka who discovered the idea of the honey-extractor.

Returning to this country, among the many amateur bee-keepers who have been of great service to the bee-keeping world, he names A. I. Root, Prof. A. J. Cook, Samuel Wagner (founder of the *American Bee Journal*), Thomas G. Newman, F. Danzenbaker, and Arthur C. Miller, the inventor of the hot-plate foundation-fastener.

Skipping across the ocean once more, Rambler mentions J. Mehring, a German, who invented comb foundation. Also Prof. Cheshire, and Thos. Wm. Cowan, editor of the *British Bee Journal*, and inventor of the Cowan honey-extractor.

As Rambler intimates, the foregoing are only a few of those who while only amateurs in the pursuit of bee-keeping, yet did much to bring it up to its present high place among the useful businesses of the world. Surely, no amateur bee-keeper need be ashamed of his place or efforts, either in the past or present. May his tribe increase, and continue to bless the craft with bright and helpful ideas.

Pure Stock vs. Crosses.—A *Stray Straw* in *Gleanings in Bee-Culture* is as follows:

A first strain of bees is very desirable for the sake of continuing good qualities without change. But the "first strain" idea may be worth too hard when it comes to the matter of improvement. With a strain so fixt that there is no possibility of variation, there is no possibility of improvement. Continuation of good traits comes from fixtness. Improvement of traits comes not from fixtness, but from variation. The trouble with a cross is that its characteristics are not fixt, but that does not argue against the possibility of greater improvement in the cross, and then it is the province of careful breeding to make that improvement fixt. I am an advocate of pure stock; but if I had the purest and best Italians on earth, and a cross that would beat them in storing by 50 percent, I'd drop the purity and try to fix that 50 percent. —Yes, but I believe you will find that crosses would have a very strong tendency to sport back to the original stock, either one of which would be poorer than the mixture. Editor.]

There is a somewhat sharp conflict between the *Straw* and Editor Root's comments; but not an irreconcilable one. Both views are correct. The progeny of pure or thorolored stock is likely to continue the qualities of the parents. The progeny of a cross is likely to hark back to the qualities of one or the other of the parents, selecting perhaps some of the least desirable traits. But there is a possibility, also, that there may be a sporting toward good as well as bad qualities. In the hands of the ignorant and careless, a cross is likely to run

much more rapidly to the bad than pure-bred stock. In the hands of the careful there may be more poor than good in the progeny of the cross, but by careful and severe selection there is a possibility of something that may be an improvement on the pure stock on either side from which the cross originated. It is a question for each one to decide for himself whether he will try the more hazardous plan of breeding for improvement from an unstable cross, or the safer plan of breeding from pure stock.

"Bees Do Nothing Invariably" is a saying attributed to Mrs. Tupper, and there is much truth in it. To establish any general rule about bees, there must be no little observation. Because you see bees do a certain thing on a certain day, you are not safe in saying that all bees invariably do the same thing every day. What is true at one time may not be true at another time. What is true one season may not be true the next. What is true in one place may not be true in another place. Laugh as much as you will at the frequent recurrence of the phrase, "in this locality," in many cases locality has a large influence.

As illustrating this matter, one man, having made careful observations, says he has found that when a bee brings in a load of pollen it brings no nectar, and *vice versa*. Another man, observing just as carefully, finds a full honey-sac in bees carrying pollen. In order to establish a general rule on the subject, there must be repeated observations, all the better if made by different observers in different places and at different times.

C. Davenport says on page 776 (1900), that he has found hundreds of bees carrying both pollen and honey, while an Ohio professor found bees carrying only one at a time. Which was the more exceptional case? The general opinion has probably been in accord with Mr. Davenport's view, but it is doubtful whether many have closely observed. If it is safe to venture an opinion, it is that careful observation will show that the popular opinion is in general the correct one, and the coming season may find many to substantiate Mr. Davenport's testimony.

Another illustration may be found by referring to pages 530 and 777 (1900). The observations of "Rip Van Winkle" do not entirely agree with those of Prof. Cook, as to the matter of scouts, and as to the reason for clustering. The questions are interesting, and may possibly be of practical importance. There is no lack of testimony that scouts are sent out by some colonies before the act of swarming. In aparies where swarming is anticipated by dividing or other means when the condition of the colony shows that swarm-

ing is in prospect, it is not an uncommon thing to see a number of bees busily engaged day after day in cleaning out a hive containing empty combs, when as yet no swarm has issued. But when a swarm clusters, and remains clustered 12, 24, or more hours, it seems reasonable to believe either that no scent had been sent out, or that their search had been unsuccessful. The fact that bees with a virgin queen are not so sure to cluster as one with a laying queen gives color to Prof. Cook's view that a swarm clusters to rest the queen. On the other hand, discredit is thrown upon that belief by the fact that in apiaries with clipped queens it is a thing of frequent occurrence for swarms to settle without any queen. Why should they settle to rest the queen when no queen is with them? Or do they do so on the general principle that a queen ought to be with them, and that she ought to be tired?

In all these disputed matters, careful and repeated observations made at different times and under different circumstances will help to general conclusions, and in the meantime it is well to bear in mind that "bees do nothing invariably."

We Wish to Thank all who have written such kind letters referring to our recent misfortune, occasioned by the fire on the floors above us. Our "watered stock" is drying out again, and soon we will be going on as before. We feared that the old American Bee Journal might be delayed, or miss a number or two, but we were able to get it out so that our readers would scarcely know that anything unusual had happened here.

Weekly Budget

SOMETIMES

The land that rocks the cradle
Is the land that rules the "Maybe,"
But "The land that rocks the cradle," 's rare
Is the land that stinks the baby
W. W. MITCHELL, in *Progressive Bee-Keeper*

MR. T. F. BINGHAM, of Clare Co., Mich., writes Jan. 4th:

"The weather is fine, and the wintering prospect outdoors is better."

MR. N. D. WEST, of Schoharie Co., N. Y., writes Jan. 2d:

"It is zero weather this morning; no snow, good wheeling, and bees are quiet."

THE AUSTRALIAN BEE-KEEPER is guilty of the following

Juggling him — "Elo, Sun! Woe's departed with your face and hair's! Got de eyes!"
"No! I got de toes!"

EDITOR HUTCHINSON, of the *Bee-Keeper's Review*, says

"A pin, if a good one, is often quite useful. For instance, at the banquet held at Niagara Falls during the Ontario convention, there was an addition to the green color of the water in the rapids, just below the falls, and some curiosity expressed as to what this color was due, when some one suggested that it was green because it had lost one nail."

MR. WM. A. SELSER, of Philadelphia, we learn in a letter from him dated Jan. 15th, lost his beloved sister, by death, last month. We had the pleasure of making her acquaintance when stopping at Mr. Selser's home a year ago last fall, while attending the National Convention. Among other things in his letter, Mr. Selser says:

"She was so helpful to me in my business; from the very start she helped bottle honey. Ten years ago, when I first began the idea of bottling, there was no end of mishaps and drawbacks caused from lack of experience on my part, and loss of hundreds of dollars in little accidents from the lack of knowledge as to how to do it right: I would become discouraged, and feel like giving it up, when she would cheer my heart with encouraging words, and take right hold and try again, and try to show me where I was wrong. We would work side by side with my wife and nan, week after week, to make it go. For the first few years she did all the labeling, then as my business increased, and I had to employ a larger force, she took charge of the molding of some four tons of beeswax in 1-ounce, 4-ounce, 8-ounce, and 1-pound cakes, packing them in boxes made for the different sizes, and getting them in shape to ship to my trade in Baltimore, New York, and Boston. She also put up a large lot of sections and frames for my made-up hivesales in spring and summer. And in all the years she would never accept one cent for her services; and upon the anniversary of her birth, when I would desire to remember her in a substantial way, she would say: 'Now, brother, you are doing too much for me.' Her life was one of unselfishness, and the very idea of pay would take her real pleasure out of her service."

"The pecuniary loss is the smallest part to me, but her bright, sunny, Christian disposition, so encouraging at every turn, will be one that I will ever miss, and leaves a place that never can be filled. We had her body away on Dec. 24th, her Christmas was with Christ, the author of it. We left the New York office to bring her home on account of appendicitis; she was sick only six days."

In addition to our own sympathy, Mr. Selser will have that of all the bee-keeping friends in the departure of his sister. But his loss must be great gain on the other side, where only character is valued. And then there is no little gain to those who are left behind, for the influence of her devoted life, and example will ever remain to bless those who knew her, and be to their memories as pleasant as the sweet fragrance of beautiful flowers.

HONEYED BAKED APPLES—MR. A. E. WILCUT sends us the following which he clipped from some paper:

"In baking apples, honey for sweetening is truly delicious. Wash the apples and core them, but do not peel, a bit of cinnamon may be put in the holes made by removal of the cores. Put the apples into a baking-pan, with just enough water to cover the bottom of the pan. When the apples are baked for 20 minutes, add the honey and bake them frequently until done. For very sour apples use a half pint of honey to every six apples. Eat hot or cold, with or without cream, they are good."

We publish this same information several years ago, and we were quite certain it originated with the bee-keeper who then sent it to us.

MR. W. L. COGGESHALL, of Tompkins Co., N. Y., writes us that it does not look very bright for his bee-keeping in Cuba, as signs of diseased brood are appearing. On page 220

1900 it was mentioned that Mr. Coggeshall had shipped a lot of bees to Cuba, expecting to carry on the business there.

MR. J. E. CRANE, of Vermont, has an article in the *Bee-Keeper's Review* telling how his bees helped to build his beautiful home, a picture of which forms the frontispiece. He says that when young he was quite an invalid, and the doctors advised living on a farm, but he was not able to do heavy work, nor had he the capital to employ some one to do it for him. No one in his locality had made a business of bee-keeping in those days—about 40 years ago—the some of his neighbors kept bees, and were able to sell some honey in good seasons. He read the books of Quinby and Langstroth—there were no periodicals devoted to bee-keeping in those days. He was led to believe that he could sell enough honey to employ the needed help to work on his farm, even if he did not produce enough to make a living at the bee-business. He began in a small way, as all beginners should do, and did not get a pound of surplus the first season, as it was a very poor one. The next year his colonies averaged 100 pounds. He then increased his apiary until he had six or seven hundred colonies all his own. He used frame hives from the very first, and had Italian bees. The price of honey averaged 30 cents per pound above the cost of selling, being fully double what it is today.

He thinks that more failures in bee-keeping come from increasing too rapidly than from any other cause. He has stuck to his bees thru all kinds of seasons, and believes that they will pay as well, ordinarily, as any other branch of rural industry. After 35 years of work with them he is more interested than ever. He thinks that it pays to persist in the business rather than to sellout when a poor year comes, or let them die, and go into something else. He realizes that many parts of our country are unfit for keeping bees profitably, the same as would apply to wheat-growing or fruit-raising, and that there is nothing to be gained by trying to believe that bees can be made a success everywhere. The way to discover a good location is to investigate the flora, and consult those who have kept bees some years in such localities.

THE ONTARIO BEE-KEEPERS' ASSOCIATION elected the following as its officers for 1901, at its meeting held at Niagara Falls last month:

President, John Newton, of Thamesford; 1st. Vice-President, J. D. Evans, of 2d. Vice-President, Jas. Armstrong; Secretary, Wm. Couss, of Streetville; Treasurer, Martin Enright; Foul-Brood Inspector, Wm. McEvoy, of Woodburn; Assistant Inspector, F. A. Gemmill, of Stratford.

Woodstock, Ont., was selected as the next place of meeting. We learn that the last meeting was the best ever held by the Association. We hope soon to find room for an epitome of at least a portion of the proceedings.

MR. G. M. DOOLITTLE has been down in Arkansas for several weeks, looking after a farm in which he is interested. He expects to be at his home in New York State again about Feb. 1st. Among other things he says in this letter to us dated Jan. 12th:

"I do not see why bees ever need to die in wintering bees here. Sebastian Co., Ark., if they have food enough, for more than one half the days since I have been here have been warm enough for them to fly, and the sun has shone every day but two."

Convention Proceedings.

Report of the Proceedings of the 31st Annual Convention of the National Bee-Keepers' Association, held at Chicago, Ill., Aug. 28, 29 and 30, 1900.

BY DR. A. E. MASON, SEC.

(Continued from page 39.)

Pres. Root—We will next listen to the paper by George W. York, on

HOW TO SHIP HONEY TO MARKET, AND IN WHAT KIND OF PACKAGES.

While this subject is ever one of greatest interest to those bee-keepers who make the production of honey a real business, still it is also a topic on which it is almost impossible to say anything new—especially for me to do so.

Unquestionably, the "how" to ship honey to a distant market is by freight, every time, and for two very important reasons, viz.: First, the transportation charges are much less than by express; and, second, the comb honey so shipped is more likely to arrive at its destination in good condition.

SHIPPING COMB HONEY.

In the shipping of comb honey great care must be used in its preparation to withstand the necessary handling in transit. Judging from personal experience, and also from somewhat extensive observation in the Chicago market, the only safe way in which to put up comb honey to stand shipping successfully is first to put it into non-drip cases, having a follower-board at the back of the sections, with newspaper wadded up and crowded in back of the follower.

After that, the cases of honey should be placed firmly in a large crate whose upper side-pieces extend out and beyond each end of the crate about six inches, to be used as handles for carrying between two men. In the bottom of the crate should be put a bed of straw or hay, to act as a cushion under the honey-cases. Then, when putting the cases in they should be so placed that the glass side of each shows thru the crate. This will be an aid to the freight handlers, revealing the contents, and thus suggesting care in moving the crates.

It is not a bad thing to put hay or straw on top of the cases before nailing the top slats on the crate, so that should it accidentally be turned upside down, the honey would not be injured.

But in addition to all the above care in packing comb honey for shipping, it is also well to mark or tack on this precautionary notice, in large letters, COMB HONEY—HANDLE WITH CARE.

If comb honey is prepared for shipment as above directed, precious little of it will suffer any when shipped, no matter what the distance, nor how often it may be transferred from one railroad to another.

CAR-LOAD SHIPMENTS OF COMB HONEY.

For car-load shipments of comb honey no crates are necessary. Simply see to it that the cases are placed solidly in the car, in such a way that the combs are parallel with the railroad track. This is necessary in order to avoid breaking down of combs from the sudden starting or stopping of the cars. The bumping of freight-cars is simply an awful thing; hence every case of honey must be securely fastened. It will do no harm to put a light bed of straw or hay on the floor of the car before putting in the cases of honey. Even if not really necessary as a cushion, it would serve to keep the bottoms of the first row of cases clean.

If you wish to keep the tops of the top tier of cases neat and clean in the car, the whole can be covered with newspapers, or other paper, tacked down lightly. Or, what is better, a large canvas covering can be used, and after the honey is unloaded, this canvas can be returned by freight to the shipper, and thus used over and over again. It pays to keep comb-honey cases absolutely clean. We all know how dirty and dusty one becomes when traveling even in the comfortable upholstered passenger coaches; but how much worse it must be in a rough old freight-car!

SHIPPING EXTRACTED HONEY.

It will not be necessary to say much on the shipping of extracted honey. Simply put it up in good 60-pound tin cans, two in a box, and send it off to market by freight.

Now, I know there are some large and most excellent producers of extracted honey who prefer to use wooden barrels for holding and shipping their honey. No doubt that is all right for them, but I don't advise it. Of course, I am not going to try to compel them to use tin cans if they prefer wooden barrels. I would simply say, I believe that perhaps three-fourths of all the extracted honey produced in this country is now shipped in tin cans; and I further believe that within ten years practically all of it will be put up in such packages.

I have no doubt that the barrel has the advantage of cheapness, and is also more easily rolled around than two square cans in a box. But for a strong tendency to spring a leak, and for a miserable job of digging out candied honey, you always can count on the barrel.

For reliequifying, for selling in uniform single-package amounts, for nearly every desirable thing one wants to do with extracted honey, I always commend the 60-pound tin can.

Now, I believe I have not offered one new idea in this whole paper. But it's not my fault. I didn't solicit the job of writing it. It was forced upon me—likely to fill out the program, or because somebody else declined the stupendous honor (?). But no matter now just why I was prest into service for this special occasion. The subject, as well as the paper, is before you for discussion. Both are warranted to take in meek submission whatever you may feel disposed to administer.

GEORGE W. YORK.

Pres. Root—You have the paper before you; now is the opportunity for discussion. On the suggestion of some one the discussion yesterday and the day before on this subject was deferred till after the reading of Mr. York's paper. Now is the time to discuss all these things.

W. J. Pickard—Two years ago I shipped 250,000 pounds of honey in barrels. I did not have any loss: I got paid for the same amount of honey that I shipped; but this year I was advised by our old friend, Mr. York, to use cans. We have used cans to our regret and sorrow. We filled a can to get ready to send away and found it bursted on the bottom and running all over the floor. Or, we would get a can full and get ready to send it away, and find a nail hole on the top or side; all these things we have had. Fill a good barrel with honey and roll it off into a corner and it is sure to be there the next day. We paid about 90 cents for cans; we use a barrel that will hold 350 pounds for 90 cents. It takes a small boy to roll a barrel, and takes a man to handle two 60-pound cans.

C. A. Hatch—I have used honey-cans almost every year, and I have used barrels also; and I have lived in the same county that Mr. Pickard has worked in nearly all my life. I have had more loss in one season with barrels than I ever did in all my experience with cans. I have had 350-pound barrels of honey, the head drop out, and the whole contents run out into a man's wagon-box so it was all lost. The first intimation he had of any disaster was that his feet and lines were wallowing around in honey.

Mr. Taylor—Difference in location!

Mr. Hatch—It isn't the location; I have filled cans from Wisconsin, Arizona, California and Colorado, all the same, from one end of the country to the other. I endorse every word that has been said by Mr. York, but laying all jokes aside, there is this condition about the two packages: If you have a good cooper and know just where you can get your barrels at a reasonable price, and know you can depend on them, the honey that goes to bakers and manufacturers should be put in barrels; but if you want it for retail grocers' trade, you can't beat the can. We have to study our market and find out how honey is consumed, and then put the honey in the package that the market demands, no matter what our opinion is. It was said you have to pay 90 cents for cans; that must be a mistake: the cost is about 1 cent per pound if put in new cans, and about a half a cent if put into barrels. Let me tell you an experience I had with barrels. There was a cooper running a large manufacturing establishment near me, and the man I had been getting my barrels from moved away, and I thought that as long as I could get barrels from that cooper I was all right, but in this case I had to get new barrels, so I told him to send me a sample of his different kinds of barrels that he thought would do for shipping honey. There was one that I thought I would measure and estimate what it would hold, and so I commenced pouring in water at the

pump. I poured and poured; thinks I, that holds an awful sight of water. I thought I would examine it, and I went around the barrel and there it was coming out in a big flat stream as fast as I could pour it in; and, mind you, that was a sample, not regular stock. It was the case with samples, what would his regular goods be? Only last year I bought five-gallon cans and on taking some of those to market one of them fell down and I lost nearly one-half, besides it dented the wagon-box and all the other cans.

Mr. Pickard—I wish to call the gentlemen to order. He has his face from me, and I can't tell what he is saying. Take the platform and then we can all hear.

Mr. Hatch—I have said just about all I had to say, any way; but the trouble with Mr. Pickard this year is, he got a few second-hand cans. It must have been some fault in his management of those cans; I filled many more than he did this year out of the same lot, and I had to solder only four or five, and found one rusted on the side so it would leak. Let me tell you a little experience of a friend of mine in loading barrels. We had some 350-pound barrels; two men were handling them and were getting one of them up into the wagon, and the end of the barrel slipped and came down and took the end of his finger off; he couldn't do that with a can. Another time, I myself was hauling honey to the city of Winona; I was delivering a 350-pound barrel in an express-wagon. Crossing the railroad-track ahead of an engine, it tipped over and caught me between the edge of the seat and the barrel; if I had not been in a square position, my arm would have been broken; as it was, I had to carry my arm in a sling a day or two. Every time you handle a barrel with a lot of honey, you have to cooper it. Mr. Pickard has just said if you rolled it up in the corner you would find it there in the morning. If you take it to the depot, you have to cooper it over before it goes on the car; when the man gets it in Chicago, he has to cooper it over unless he puts it in a damp room; if he takes it from a damp room and puts it in a dry room, he has to cooper it over; it needs constant watching. If you have cans and put them in there, they are there to stay until the market takes the honey off your hands.

F. Wilcox It is hardly a question of location. Mr. Pickard, Mr. Hatch and myself are practically in the same field—from the same place. Mr. Hatch has said about what I intended to say, so I merely agree with him. What I want to say is on the question of market. If the honey is to go to the wholesale buyers, like the National Biscuit Co., use small barrels and half-barrels; it gives them the best satisfaction. But if it is to be consumed by the grocers, by all means I would have five-gallon cans, or small ones, and for reasons which have already been given. The reason for using barrels is that they are cheaper; it costs from 20 to 30 cents per 100 pounds of honey for half-barrels, and from 60 to 65 cents for cans; that difference alone makes all the difference between a profit and a loss when buying and selling honey; and you also sometimes have a loss by having the honey soak into the wood. I prefer to have barrels painted; paint them, then the honey may not ooze out in warm weather thru the pores.

N. E. France I don't want to bother with tin cans. Both Mr. Hatch and Mr. Pickard appreciate the tin can in its place. I want to call attention to barrel cooperage. Unfortunately, too much of our barrel cooperage has not been properly done, and again, unfortunately, the masses of the bee-keepers spoil that cooperage by soaking it up before putting the honey in it. I have barreled my honey for over 21 years without five pounds of loss over that whole time. In order to make a barrel that is tight, we must kiln-dry the timber; then have iron hoops that we can "drive home," and then keep it dry. This year in the same county where these two gentlemen are living, I found a man with 27 barrels of honey, and to my surprise he said, "What is the reason that I can not make my barrels hold?" I found that he poured boiling water in the barrel before filling with honey, and then after filling it rolled it into the sun, and I don't wonder the staves all fell down as quickly as it got daylight. I buy my barrels in the winter, kiln-dried, and put them in a dry room, and just before filling dry them again until they are thoroughly dry, and I will warrant those barrels anywhere. Whether you use barrels or cans depends upon the market; each has its place.

Mr. Pickard Mr. Hatch seems to think he has had a great many mishaps, cutting off his fingers, and toes, and one thing and another, letting his barrels fall. Last year I handled between six and seven carloads of honey, and never lost a pound by any such accident; I never lost any honey in shipment; everything seemed to be all right; barrels are a great deal cheaper and easier to handle. I un-

loaded some honey last week at our depot in 60-pound cans. I had to go right down and take the honey and lift it up bodily from the platform. I wish Mr. Hatch had been there to lift them. Had I had it in barrels I could have rolled them right out. I would like to ask Mr. Hatch, Who buys our honey? Where does it go? Where does the honey of the world go—to the table? I don't find it so. I find our honey goes to the manufacturer. My experience with what manufacturers I have known, is that they want it in barrels. I was in a factory not long ago and said to the manager, Which way would you rather have it, in barrels or cans? He said, "Barrels; with them I can roll it right out." I wouldn't give you a cent a can for honey; barrels are cheaper, and, as Mr. France says, if you keep water out of barrels you won't have any leakage.

D. H. Coggeshall—in our vicinity, the last ten years, we used kegs, and got good ones; we don't want any second-hand kegs. They hold 210 pounds. Now we get them hooped with flat wooden hoops, 12 on a keg. We got our kegs last February for this year; they are scattered around, most of them, in our different outhouses. We drive those hoops thoroly before we put the honey in, and don't have any leaking to amount to anything; we ship these kegs and are bothered hardly any, and it is a half a cent a pound less expense than it is to put it in cans, and we can sell it for just about the same price. Our New York market, for manufacturing purposes, wouldn't give us any more for it in cans than they would in the kegs, which are made of white poplar, as I understand it. They are thoroly put up in every respect.

Mr. Moore—My experience in this respect has not been very satisfactory. I notice there isn't any certainty that there would be no loss either in barrels or kegs. I know Mr. York told me he got a can the other day that had only about 10 pounds of honey in it when it arrived. It is well known that the Dadants are among the heaviest honey-producers of this country. They state practically what Mr. France did, that barrels are absolutely certain with them if absolutely kiln-dried and well coopered.

Mr. Hatch—I would like to ask Pres. Root what kind of packages their customers prefer?

Pres. Root—I can't say what kind of packages they prefer; a few years ago it seemed to be barrels, and now it is coming more and more in cans. My own personal experience has been more favorable with cans. The first year of foul brood with us dates back to leaky cans. The cans came on the train, and before we could get them off, the honey leaked down on the car and about two weeks after that foul brood started in our apiary. That would not be an argument against cans.

H. N. Chandler—I have had considerable experience with tin cans. I would advise those going to use tin cans not to use second-hand ones. [Applause.] If you use second-hand cans, and lose one can of honey, you have lost enough to pay for the difference between quite a number of second-hand cans and new ones. We tried second-hand cans and lost more in one year than would have paid for the difference between second-hand cans and new cans for five years; I put up 400 or 500 cans a year.

J. A. Green—I want to count myself among the barrel men. One after another has made most of the points I expected to speak on. I will say that my experience has been, with Mr. France and others, that the barrel is almost absolutely certain, while I lost considerable honey in filling new cans, and from honey that was shipped to us in tin cans. There is one barrel that hasn't been spoken of, the hard-wood barrel that Mr. Dadant has used for years; it is a second-hand alcohol barrel. You can get them at almost any drug-store; they come in two sizes, one holding about 350 pounds and the other about 550. Of course, it depends upon your market; my market demands, or at least will take just as readily, those large barrels. When I get an order for a barrel I send one of those 550 pound barrels that cost me \$1.00 or \$1.50 apiece. If they have not been kept a long time in a perfectly dry place, put them in the sun and then tighten the hoops. Somebody said you could not use barrels in Colorado, the climate is too dry. That is what you want; put the barrel in the sun where it will get perfectly dry, then drive down the hoops and fasten them, and you have something that will hold.

Mr. Dunne—Old alcohol barrels are coated with glue, and is the glue any detriment to the honey?

Mr. Chandler—I think it is shellac.

Mr. Dunne—No, it is glue.

Mr. Chandler—I used to wax the barrels inside, or use paraffine, but late years I have not done it.

Mr. Moore—My brother has used alcohol barrels for a

number of years, and I heard him speak in terms of commendation of them. If well coopered they will hold almost anything; I never heard him say a word against them.

Mr. France—While I was down at Mr. Dadant's, I examined those alcohol barrels; I thought I would try them next year for a small portion of my honey, as a large portion of it was going to consumers; but unfortunately I could not get alcohol barrels so clean but what there would be a little of the alcohol flavor to it; therefore I discarded them. I want new packages for honey.

Mr. Hershisier—One other barrel that hasn't been spoken of yet I think is a good barrel; it is the barrel that is used by the glucose manufacturers; they use a basswood barrel, holding 650 to 800 pounds. I have used only a few of these barrels, but I find they are excellent for the purpose; they are paraffined inside; I used second-hand barrels only. In almost every large city where glucose is manufactured, I think they can be had from the manufacturers at very reasonable prices. There is another package that I saw in a manufacturing establishment in Buffalo; it came from Wisconsin. I don't know the producer of the honey that came in those packages, but they were like a candy-pail filled with honey, and had the head put in and the honey was candied. I think that was a very nice package; it would hold, I should think, about 50 pounds. Now, while I am up, I would like to ask if those basswood barrels used by Mr. France are paraffined inside?

Mr. Wilcox—I just want to say, I am sorry to see it go upon record that any member of this convention recommends the use of glucose barrels; glucose barrels filled with honey and sent to any market in the world would excite a suspicion that they had had glucose in, emptied and refilled. I would not use a glucose barrel myself or any syrup barrel, because all syrup so far as I know, is mixed with glucose; therefore I would not buy syrup barrels under any circumstances whatever.

Mr. France—In reply to Mr. Hershisier, I will say that I was asked at one of our conventions if I waxed the barrels, and my reply was no.

Mr. Abbott—I want to suggest the question, Are we not losing sight of a certain market for our honey? I have not heard any remarks on it at all, as I was out during part of your discussion. I have not heard anything said about honey for the home trade. I handle a great deal of honey during the year; but I would no more think of selling to any of my customers honey out of a wooden package than I would think of selling it to them out of a vinegar barrel. Honey, to me, is wholly unfit if it has been in wood at all. I don't know of any way to get honey out of wood without injury; if you scrape it out, you will scrape the wood; it is always filled more or less with sediment. I notified the Dadants if they ever send me honey in a wooden package there won't any more honey come into Missouri address to E. T. Abbott, because I do not want it; I cater to fancy consumers, and I can't use that kind of honey at all. Just now I am using bottles. I am just hunting for somebody that has nice, bright, ripe honey in clean, new cans, where I won't have to pick out the dead bees and pieces of old comb, and strain all sorts of things out—sometimes pieces of cob-pipes and plugs of tobacco, and various other objectionable features. It is all true; I have had that kind of experience, and I simply ask you now. Wouldn't it pay you better if the large producers would cater a little more to this trade? We people who do not produce honey, but sell a great deal of it to consumers, will find you a market for your honey if you give it to us in the right shape. I remember, not a great while ago, I got some honey from a prominent bee-keeper in Iowa; he sent it down to me in some rusty, nasty, stinking looking cans, and it made me sick to look at the cans, much less at the honey. I strained bees' wings out of it, and all sorts of stuff, and had to sell it at less price than I gave for it in order to get rid of it; it came from a prominent bee-keeper, a man who writes for the bee-papers, and thinks himself an authority. I can't sell that kind of honey. I am not saying this to take sides in favor of barrels or cans; I am telling you what we want. Will you not remember us when you are putting up your honey? We don't want any honey in barrels, or any kind of wooden package; we want it in nice, clean, new tin cans.

(Secretary—Pretty good advertisement for Mr. Abbott, and for producers, too.)

(Continued next week.)

The Premiums offered this week are well worth work ing for. Look at them.

Rearing Queens in Early Spring—Some Advice.

BY G. M. DOOLITTLE.

A CORRESPONDENT writes as follows: "Will you please tell us thru the columns of the American Bee Journal how early in the spring we can commence to rear queens, taking the stage of advancement in drone-rearing as a guide? In other words, if we commence to rear queens when we see larva in drone-cells, will drones from that larva be on hand to meet the queens when they are ready? If so, in this way we can tell just when it will do to commence queen-rearing, no matter whether we are located in Canada or Florida."

If the correspondent, or any one else, uses any of the plans by which larva from 24 to 36 hours old are given to the bees from which to rear queens, said queens will perfect and emerge from their cells in from 11 to 12 days from the time the cells are started, as a rule, for, by an experience covering a period of 30 years I find the average time, taking the seasons as they come, and the season from early spring to late fall, for a queen, is three days in the egg form, nearly six days in the larval form, and seven days in the chrysalis, making a period of nearly 16 days from the time the egg is laid to the time the young queen emerges from her cell. Very warm weather will hasten the development during all stages, to a slight extent; while very cool weather, or inactivity with the bees, as in the fall of the year, retards this development. I have never known this development to be hastened to a greater degree than having the queens emerge from their cells in 15 days; but I have had it so retarded in the fall of the year, especially where queens were reared in upper stories, that they did not emerge from their cells, or become fully mature, till 20 days from the time the egg was laid by the mother queen. But, as I said before, about 16 days is the rule, and it is one which can be depended upon in nine cases out of ten.

Then, as a rule, the young queen does not go out to meet the drone till she is from six to eight days old, seven and one-half days being about the average during the summer months, so we have the time as being not far from 17 to 20 days from the starting to rear queens to the time they would naturally fly out to meet the drones, where everything is favorable. Occasionally a queen will fly from the hive, evidently in search of drones, when from four to five days old; and I have known them to be 28 days old before becoming fertile, but in nine cases out of ten queens are fertilized when from seven to eight days old, when the weather is favorable.

If the above is correct, and I believe it is, then it will be seen that we shall want flying or mature drones in 17 days, at least, from the time we start our queen-cells.

I have not as carefully observed the time of the maturing of drones as I have that of the queens, but from the observations I have made along this line, I find that the drone is in the egg and larval form about 10 days, or one day longer than the workers, and about 14 days in the chrysalis form, making a period of about 24 days from the time the egg is laid to the emerging drone.

From six to eight days after the drone emerges from the cell it goes out for its first flight, to void excrement, mark its location, etc., similar to what the worker-bees do, which is called their first play-spell, during which they mark their location also. After this first flight they go out every pleasant day from 12 to 3 o'clock, p. m., to meet the queens, if they are to be found, so that we have about 32 to 34 days from the time the queen lays the eggs in the cells for the drones, to the time they are ready to meet the queens. Therefore, as we had from 17 to 20 days from the time we commenced to rear queens to the time the queens would go out to meet the drones, it will be seen that the drone-eggs should be laid 17 days, at least, before we start to rear queens, and this would bring the time to where the drone-brood would have to be sealed from six to seven days.

Of late years I never commence to rear queens until plenty of sealed drone-brood appears in my drone-rearing colonies. Usually, I wait longer than this, the rule which I adopt being, not to commence to rear queens till the eyes of the chrysalis drone commence to change from the white

color of said chrysalis while in its first stages, to the purple color of its later stage.

And now pardon a word regarding very early queen-rearing. My advice is, don't do it, unless you are willing to treat the colony rearing them in a similar way to which a king treats a new-born heir to the throne, for any neglect on your part will almost surely result in very inferior queens. Very early queen-rearing generally results very unsatisfactorily in this locality, as the colonies used for this purpose have to be petted and pampered, by way of feeding, often in very unsuitable weather for the breeder to be out in; carried indoor on cold nights, so as to keep up the desired temperature, etc., while the colonies used for this purpose are very much retarded, about building up, and the queens do not come up to the standard of perfection, unless the care of an old veteran is used in seeing that all the requisites of a perfect development are present, which is well nigh-impossible, in this locality, during March, April, and the first half of May. June, July and August are the months, during which the rank and file can rear good queens with the least trouble here at the North.

What is Meant By "Cooling Beeswax Slowly?"

BY F. GREINER.

IT will now seem as tho all the difference that existed on the matter of how to produce nice yellow wax will be laid by, or at least as soon as we fully understand the meanings of the terms used. I do not think there would have been any difference at all had it been clearly defined where the cooling is to commence and where to end. An illustration of the status would be this:

The little mountain stream passing by my house answers many of the purposes of the city water-works. We use this water for washing, rinsing, etc. When I catch a pailful of this water I can notice particles of foreign matter, perhaps soil, vegetable matter, etc., in it, and I have found out, by experience, if I give the water a little time all visible particles will settle down to the bottom of the pail. Along comes a gentleman from another clime. "Nonsense," he says; "after the water has become solid, no amount of cooling will cause any of those impurities to settle. It will remain just as it is forever." And he is right, perfectly right. All the difference is, I was experimenting with liquid water, and the other gentleman had the frozen article in his mind. As soon as we find out what the other means we agree perfectly.

Beeswax "freezes" at a much higher temperature than water, but that does not alter the case any. Particles of dirt or other substances can not settle any more after it has become solid. I don't think any person of sense had expected it, even should the cooling process be carried to the greatest extreme. In this respect frozen water and frozen wax behave exactly alike.

In my 25 years' experience as a bee-keeper it has happened at least several times that I have melted up wax. With my facilities I never have been able to melt a batch without its coming to the boiling-point. This is exactly the point where the cooling commences, with me. I have explained a number of times in other papers how this cooling (slowly) should be managed. The impurities in the wax must have time to settle while the latter is in a *melted and quiet state*. I consider the cooling process ended when the wax solidifies, altho my idea may not be exprest properly.

Naturally Built Combs, vs. Comb Foundation—A Reply.

BY C. P. DADANT.

IT is only since my return home from Europe that I have noticed the two articles of Mr. Deacon, of South Africa, published August 10th and 23d, 1900, in reply to some articles from me published in 1897. I had concluded to allow a similar length of time to elapse, between his notes and my next reply, as were put between our former discussions; but some of our friends seem to be impatient for a word from me.

I will leave aside the very important facts that the use of comb foundation secures straight combs and worker-combs exclusively, altho all who have tried these matters know the importance of them, and Mr. E. A. Hodsell, on page 630 (1900) has already fully covered these points.

Mr. Deacon lays great stress on Simmins' experiments as to the cost of beeswax to the bees. I must acknowledge that if I had ever read of these experiments I had forgotten them. But they seem to me to be faulty from the start. Mr. Simmins experimented with a swarm weighing three pounds, but does not seem to have taken into account the quantity of honey those bees had in their honey-sacks when hived. Bees that swarm, or that are disturbed and transferred from one hive to another, always gorge themselves with honey to the utmost, and in the case of this experiment must have been so loaded. He figures that it took 12 4-5 pounds of honey for one pound of wax, and then goes on and deducts the quantity of honey that was consumed by the bees. I can not see the wisdom of this. Surely, bees must live while they build combs, and the cost of their board should be reckoned in the total cost.

If we figure up the cost of an article that we produce, we should count up our board while we are producing it, together with other expenses. So, in my mind, the 12 4-5 pounds is nearer the right amount than the 6 2-5 which he gives as correct, while still estimating the actual amount at even less.

Mr. Simmins is not the only man who has made experiments concerning the cost of wax. Huber, a Swiss, found that nearly 20 pounds were needed. Berlepsch, a German, made it from 11 to 20 pounds, according to circumstances. Since that time experiments have been tried over and over, and the lowest report I remember, made on a practical test, with bees in freedom, was made by Mr. Viallon, an American, with two swarms of equal weight; but he forgot to take into account the amount of honey spent for the brood reared by the hive to which full combs were given, when comparing with the swarm that had to build the combs, and yet he put the amount at 7 to 8 pounds. The quantity would probably have been raised to the general average of 11 or 12 pounds had he taken the brood-rearing into consideration.

Authorities confirm the high cost of comb. Prof. Cook says that his own experiments confirm Huber's test of 20 pounds being needed. T. W. Cowan (English) puts it at 13 to 20. Cheshire (English) says it takes "many pounds."

The assertion that wax secreted is wasted when foundation is furnished, does not hold together. Bees do secrete a little wax when the crop is abundant, and they always have good use for it, for no one ever can furnish their foundation in such shape that they can fill every part of every comb. Any bee-keeper who uses foundation has seen where they put the wax secreted, for it is whiter than the other. There are always plenty of nooks and corners to fill, and combs to seal. But when there are no combs at all, we all know that they have to hang in festoons and remain idle, probably because they must wait till the honey is digested and the wax is secreted, and because there is no room for more honey till some comb is built. So does the queen lose time, when they are hived upon empty frames, and they have to build combs before she can lay.

Mr. D. makes a play on words about the expression "drawing out" the foundation. He implies that we mean that the bees get behind each other, and, pulling at each other's jacket, thus stretch the foundation, by pulling on it. But he surely knows what we all understand by these words. I use them because everybody does, and we all know that the bees manipulate the wax with their mandibles, and that it is quickly done. A comb of foundation given to a strong colony in the evening will often be all drawn out and eggs laid in it by morning. Are they not also always remodeling their naturally built combs? When combs are whitened, at the beginning of a harvest, it is very difficult to tell just where the bees began, and we can see that they have remodeled a portion of the old comb to mix the new wax with it.

Mr. Deacon denies my assertion of the Americans being practical, and says that they "take an amazingly long time to realize the uselessness of a thing." I must say that in the matter of comb foundation even the all-wise Britishers are also apparently deluding themselves, for, besides what they make, they import thousands of pounds of this *useless* foundation into Great Britain. They are badly in need of a few arguments from our South African friend.

But this manner of denying the correctness of progress, after so long a time, reminds me of the French editor Hamet, who, 20 years after the invention of the movable-frame hive, still persisted in calling it "a puppet show," and the honey-extractor "a useless toy."

And as to the practical tact of our Americans, I feel

free to speak of it, being a foreigner myself, by birth. The honey-extractor, the bee-smoker, the much-abused foundation, are all European inventions, but take the bee-journals of 25 years ago, and see who took hold and improved and made these things practical and put them to use. Americans, of course. The Europeans only followed. Hancock Co., Ill.

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

THINK NEITHER HONEY NOR SUGAR CAUSED IT.

That life-insurance doctor on page 809, he was presuming in crediting sugary urine to the consumption of honey. Moreover (altho a defiance of authorities, and possibly a sad mistake of mine), I will go further and make a pretty decided statement of my private opinion that neither sugar nor honey had anything to do with it. Pestilent old-grannyism has not all been eliminated from medical practice yet; and I doubt whether the present warfare against sweets is any better founded than the warfare of 60 years ago against drinking water. At that time almost any patient could be depended upon to die if he succeeded (by bribery or otherwise) in getting a cool drink of water.

A THREE-SCORE-AND-FOUR BEE-KEEPER.

Most of us will have to take off our hats and make a bow to Dr. Besse, with his 64 years of continuous bee-keeping. We can't even fib about it when the boys all know that our cradles are not yet 64 years back. And the boy who earns a hive of bees this summer, and continues in the business 64 years, what sort of hive and manipulation will he arrive at A. D. 1965? Page 811.

TONGUE MEASUREMENTS VS. HONEY-STORAGE.

Anent the paper of J. M. Rankin, of the Michigan Agricultural College, I will confess that I have felt all along strong suspicions that dissecting bees and measuring their tongues was a deceptive and unreliable way of getting at things. I had a sort of idea that length depended much on the amount of injection with blood and other fluids incident to life, and that cutting the member off would, of course, let all fluids loose, that there would necessarily be contraction, and that the amount of the contraction would not be at all uniform—temperature, length of time the bee had been dead, and other things, playing bewildering roles. May be I'm wrong. Don't want to be out of fashion. The idea is in the air,—breed from bees whose tongues measure high. Measurement, if it is even approximately reliable, is much more to the point than honey-storage. The latter is almost hopelessly fortuitous, except to long and skilled experiment, while the former gives us something to go by *at once* if we want to improve our bees. Get the tongues, and sooner or later the tongues will get the honey. The way the publisht lengths agree with the honey-storing reputation of the colony seems to be reassuring. But the *millimeters* are rather grinding to us. Few of us have any mental picture within as to how short meters or how long meters they may happen to be. I'll come to my own rescue and yours by figuring out that the best 240-pounder bees were snouted up to over 23 hundredths of an inch, while the yellow 135 pounders scored less than 20 hundredths—the exact figures being .236 plus and .197 minus, respectively. Strikes me we have had but few publisht measurements of this sort to beat .236. And .197 is not a bad measure. Page 812.

SEEING ALL OF THE 20TH CENTURY.

"In all probability very few now living will see all of the 20th century." Editorial, page 819. Tut, tut, dear George W.! That's not the way to talk it. To defeat the microbes and add 50 years or more to average human life, is not half so wonderful a triumph—not half so wonderful a *medical* triumph—as some the nineteenth century won for us. Don't start out by telling us that the twentieth century must, of course, do less.

BIOGRAPHICAL

Mr. O. O. Poppleton, of Florida.

We are pleased to be able to present on our front page this week a most excellent picture of O. O. Poppleton, of Dade Co., Fla. He was born near Green Springs, Ohio, June 8, 1843. In 1855 he removed to Chickasaw Co., Iowa, where he lived until 1887, when he went to Florida, on account of his health. Excepting about two years at Oberlin College his education was obtained in the common schools.

In October, 1861, he enlisted as a private in the 7th Iowa Infantry, and re-enlisted as a veteran in 1863. In February, 1864, he was promoted to a lieutenancy, and a few months later was made regimental adjutant. While performing his duties overwork resulted in eye-trouble, which has seriously affected his health ever since. After the war he went to farming in Iowa, and married a Miss Groom, who died 12 years later, leaving him two daughters.

Dec. 6, 1881, he married Mrs. Mattie Herrick, of Ft. Wayne, Ind. On account of poor health and the very severe Iowa winters, they went to Florida during the cold seasons for several years, where they found the change of climate, with outdoor living, greatly improved his health.

When first married he was given a colony of bees in a box-hive. It so happened that in the winter of 1869 he became acquainted with a bee-keeper that is now extinct. He was very much interested in it, and very soon obtained all the literature on bees he could find, thus learning that there was a better way of handling bees than in box-hives. He soon obtained movable-frame hives, and in a year or so had quite an apiary, which, in common with many others, was almost destroyed by bad wintering in northern Iowa. But the use of chaff-hives removed this trouble for the future. On account of such poor health he made no effort to do a large business with bees, but kept from 75 to 150 colonies, spring count, and devoted himself almost exclusively to the production of extracted honey. For the last ten years that he lived in Iowa his annual crop averaged 110 pounds per colony.

More than 25 years ago he discovered the value of chaff as a winter protection for bees. He also invented the solar wax-extractor about the same time. For several years he was vice-president of the National Bee-Keepers' Association, president of the Iowa State Association, and honorary member of the Michigan Association. He has ever been a careful observer, doing his own thinking and adhering to plans which he had found successful.

Over ten years ago Mr. Poppleton kept bees for two years in Cuba, the Dussag apiary in his charge containing from 400 to 500 colonies. During the winter of 1888-89, 398 colonies gave a crop of 52,000 pounds of extracted honey, or about 130 pounds per colony—a larger gross yield from one locality, but less average yield per colony, than has been frequent with him both in Iowa and Florida.

On removing to Florida in December, 1889, and looking over the situation, he decided to practice migratory bee-keeping, keeping his bees at what is now his home in Dade Co., on the banks of the St. Lucie River, from October to June, and at Hawk's Park from June to October. His home was the best winter location, while at Hawk's Park was the best-known field for black mangrove in the State. The two locations were about 150 miles apart by water, and the bees were moved on lighters drawn by steam-tugs. His losses in all this moving were no colonies at all, about one-half dozen combs broken down, and a few dead bees in some of the hives. The four seasons he kept bees in this way gave him average yields per colony, spring count, 273, 291, 82, and 300 pounds. The mangrove was frozen down so badly in the winter of 1894-95 that he has changed the location of his bees to a place 35 miles north of his present home—a location with some black mangrove, but much inferior to what Hawk's Park was before the freeze. His average yield since 1894 has been some over 100 pounds per colony—about the same as he used to get in northern Iowa.

Owing to the poor health which drove him to Florida, Mr. Poppleton has not tried to do a large business, but has kept only bees enough to give him a fair living. He also

has a small patch of pineapple, giving from 25 to 100 barrels of fruit annually. He will increase the acreage of this fruit in the near future.

— Mr. Poppleton's wife died about five years ago. His remaining family is a married daughter and her two children living in Florida, about 70 miles north of where Mr. Poppleton's home is in Dade County; he has also an unmarried daughter living near his old home in Iowa, taking care of her aged grandfather.

Referring to his migratory bee-keeping and methods employed, Mr. Poppleton wrote us as follows:

MIGRATORY BEE-KEEPING WITH A GASOLINE LAUNCH.

Moving bees on the water has been a favorite method since ancient times wherever migratory bee-keeping was practiced. Nearly all the different kinds of boats known have been in use for that purpose. Of late years a favorite plan has been on lighters towed by steamers. These are all right if one could always secure them just when needed. Some fuse-sailboats, which are quite cheap to use, but quite uncertain and unsatisfactory. I have used both methods within the past ten years, but found them faulty for the reasons given.

About two years ago I had built for me the launch "Thelma," probably the first gasoline-powered boat in America that was designed and built especially for general apian work, such as moving bees from one location to another, carrying honey to the railroad, going from one apiary to another, etc. She is 25 feet long, 6 feet 8 inches beam, and is

Mr. Poppleton's Gasoline Launch "Thelma."

driven by a 3-horsepower "cloche" electric gasoline engine. She is what is known locally as a "skipack" model, giving for a boat of that size a low and large floor space, some 50 square feet of the latter aside from the engine space. She will carry at a time about three tons of honey, or about 60 colonies of bees in single-story Langstroth hives. Her speed is about six miles an hour on an all-day's run. The engine power is smaller in proportion to the size of boat than any other boat I know of. To have put in the next larger size of engine would have cost \$200 more, first cost, and 50 percent more per mile to run, and added not to exceed 25 percent to the speed. It costs about 2 cents per mile to run for gasoline, electricity, and oil, or less than the average railroad fare for one person. At least 20 people can ride in the boat at one time with comfort.

The picture of the boat shown herewith was taken last summer at Fort Pierce, while on my road home from Indian River Inlet with a load of bees.

The boat can also be used for pleasure-trips. Within the last month a nephew and niece from Ohio were visiting me, and the three of us spent nearly two weeks in cruising a hundred miles down the coast and back, stopping along as we pleased, to hunt fish, view tropical scenery, etc. We had a gasoline stove, cooking utensils, dishes, and beds, in the boat, and made it our home while gone.

The boat is quite a different model from any other heretofore in these waters, but has been so generally successful for an all-purpose boat that already one other has been built of the same size, and others soon will be. It would be very unpleasant for me now, if I should have to go back to the use of a sailboat or hired steam-tugs.

Dade Co., Fla., Dec. 18, 1900.

O. O. POPPLETON.

We might add in concluding this sketch of Mr. Poppleton, that we have had a personal acquaintance with him for some years, and count him as one of the best in all bee-dom. We have often tried to get him to contribute regularly to the columns of the American Bee Journal, but on account of his eye-trouble and general poor health he has been unable to undertake the work.

We hope that he may be spared many years to the remaining members of his family, and to the host of bee-keeping friends who appreciate his character and his efforts in behalf of advanced and progressive methods in apiculture.

Questions and Answers.

Introducing Queens—Supers on in Winter.

1. Will it do to introduce queens during the winter months where the old ones are too old to be of any use, or where the queen has died and left no brood? I am a beginner, have 30 colonies, and fear that there are some that need new queens.

2. They are outdoors, but all have double hives packed with dry leaves all around. I left the supers on all that are partly filled with combs, as I have no place to keep them. Have I done right? If not, what shall I do?

KANSAS.

ANSWERS.—1. Better not do anything about introducing queens till spring. It will be very hard for you to tell now whether a colony has a queen or not, for there will be on brood in the hive in most cases, even with the best of queens, and you may lose queens by trying to introduce now.

2. They are probably all right so far as the bees are concerned. But if you mean you have left on supers with partly filled sections, it will be rather rough on the sections. They will likely be darkened too much for first-class sections. But it will be hardly wise to disturb them now.

A Question on a Honey-Deal.

A sold to B 20 barrels of honey, B to pay A prompt cash on board the cars at A's railroad station. A delivered the honey at the station in good condition. When the honey arrived at B's station one barrel had the head knocked out, and the contents all gone. B made claim on the railroad company for the barrel of honey, and insists on A waiting for his pay for that barrel until he gets it from the railroad company. A insists that the honey was B's as soon as it was delivered at the railroad station, and that B should pay A for the honey, and not wait for the railroad company. Who was right, A or B? In other words, if the railroad company does not pay for the barrel of honey, who should be the loser?

SUBSCRIBER.

ANSWERS.—Unless there was some specific agreement to the contrary, it would seem that if B was to pay cash for the honey delivered on board cars at A's station, that A's ownership of the honey would end at A's station, and having fulfilled his part of the contract he should be paid the stipulated price, no matter what the railroad company might afterward do with the honey. [As our opinion is asked on this question, we would say that we agree with Dr. Miller's answer.—EDITOR.]

Judging Queenlessness and Winter Stores Externally—Management with More than Two Stories.

1. Is there any way of knowing from external appearances if a colony is queenless?

2. What is the best way of determining if a colony has sufficient winter stores? As my hives are all of the same pattern, it might be done by weighing, if known what the bees weighed. Can you tell me what an average colony will weigh?

3. How is a colony run with more than two stories—a body and a super? Does the queen circulate between the first and second, and a queen-excluder on top of the second, and the honey stored in the third story? Or should there be an excluder on the top of the first, and honey stored in the second and third? If so, is there any advantage in it? Why not use only the second story for surplus, and extract as often as is necessary?

KANSAS.

ANSWERS.—1. None so good as looking into the hive, and at this time of year it may not be easy to tell them, for queens are not likely to be laying now in the North. But you can judge something from the outside. If there comes

now a day when bees fly, and you find the bees of a colony running over the outside as if hunting for a queen, or if they continue uneasy after the other colonies have stopt flying, and have settled down to quietness, you may at least entertain suspicions of queenlessness. If you pound on a hive while holding your ear to it, there will be a response from the bees, and then a prompt quieting down if their queen is all right. It will be something more like a wail if they are queenless. In the working season you may be somewhat suspicious of a colony that appears very listless, and that carries in little or no pollen when other colonies are carrying in big loads.

2. If you find out the weight of a hive with its combs and a good store of pollen, then add to that ten pounds for the weight of the bees, you will be pretty safe in counting that any excess over this is honey. One of the best ways to tell how much honey there is in a hive is by actually lifting out the combs and seeing how much honey is present. Even then you may not be so very exact about it, for you can not tell how many cells have pollen under the sealed honey. The safe way is to make allowance for a liberal amount of pollen, for there is little danger of harm being done by too much honey in the fall or beginning of winter.

3. Sometimes one story is allowed for the queen, then an excluder, then one or more extracting stories. Sometimes the excluder is put over the second story, allowing the queen to use two stories. If 8-frame hives are used, the two stories for the queen are more needed than if 10-frame hives are used. You can use a single story for extracting-frames, but that makes it necessary to extract oftener, and makes it more difficult to have the honey well ripened. If for any reason you must have a single extracting story, it may not be a bad plan for you to extract only half the combs at one extracting, then the other half at the next extracting, and so on. That will give less chance for un-ripened honey, but will make you extract oftener than if you extracted all the frames at one time.

Removing Bees from the Side of a House.

A neighbor has a large swarm of bees in the side of his house, and wants them taken out. How could I drive them out and save them? I would like to drive them into a hive. I am told that some medicine will drive them out. They are very cross, but are wonderful honey-gatherers.

CALIFORNIA.

ANSWER.—The fumes of carbolic acid are very effective to bees, and if enough of the acid is poured into the place it will surely drive the bees. If a frame of brood be held at the place where they come out, they would probably occupy it promptly, and if it could then be put into a hive, and the hive be placed so that the bees could run right into the entrance of the hive as they come out of their hiding-place, the effort to have them ought to be successful. There is a possibility, however, that there is so much room where they are that they would merely move to another place away from their combs, and you would be no better off than before. If so, there may be no certain way to get them out without cutting away part of the wall and cutting out the combs, removing bees and combs together.

Sections Open on Four Sides—Packing Material.

I am about to buy my bee-supplies for this year, and would like advice on a few points.

1. Is there any advantage in using sections open on all four sides? I used them last year; my notion in doing so was that it gives the bees free access to any part of the surplus department easily and readily. With sections open on two sides, should a laden bee get in the department already full, she has to look around for a place to deposit her load, thereby losing valuable time.

2. Is excelsior good for the surplus department in winter?

3. Is the cork that grapes are packed in good or better than excelsior? I can get all I want of either cork or excelsior.

NORTH CAROLINA.

ANSWERS.—1. Some think that sections open on all four sides are better, for the reasons you give. Perhaps there may be some advantage in having more free communication, but it can hardly make very much difference, for if I am not mistaken, most bee-keepers cling to the sections with openings at top and bottom, and sides closed; altho some years ago much was said about sections with four bee-ways, and if they were much better they ought to have

come into general use. If a bee with a load of honey were to enter a super for the first time, and should get into a section already entirely filled, it would no doubt be a convenience to have a side passage directly into a section still offering room. But that is hardly the condition. Mr. Doolittle tells us that it is not the field-bees that deposit the honey in the sections, but that the field-bees dump their loads in the first convenient place in the brood-chamber, and then a set of bees that do not go afield carry from below into the sections. Is it not probable that these inside carriers are quite familiar with the room upstairs, so that they may go generally to those parts of the super where they are sure there is room?

2. Excelsior, if dry, may answer for packing, but planer-shavings are generally preferred to excelsior, possibly because the planer-shavings are more compact.

3. Ground cork is one of the very best things for packing, and is considered away ahead of excelsior.

Feeding Bees in Winter.

What is the best way to feed at this time of the year? I have three colonies in the cellar, and three on the summer stands packed in chaff. Is it best to feed syrup, candy (if candy, what kind?), or granulated sugar dry?

ILLINOIS.

ANSWER.—The best way is to do your feeding as soon as possible after the bees have stopt gathering, whether that be in August or later. But sometimes circumstances are such that we can not do what we would like, and then we must do the best we can. Certainly it would be unwise to let a colony starve rather than to feed this time of the year. Don't think of feeding syrup now. Giving combs of sealed honey is much better. But in all probability that's about as good advice as telling you how to feed last August, for it's a pretty safe thing to assume that you haven't any combs of sealed honey. Granulated sugar dry would be little better than so much sand. The bees couldn't do anything with it. Candy is the thing, the best perhaps being the "Good" candy, made with powdered sugar and extracted honey. Warm the honey (I'd say heat it, only you might then burn it, and that would make it poison for the bees), and stir into it all the powdered sugar you can. Then knead it like dough, adding all the sugar you can work in till you have a stiff dough. Put a cake of this, perhaps an inch thick, over the brood-frames, and cover up warm. Plain candy, made of granulated sugar, the same as any confectioner makes, will also do.

Robbing—Making Comb into Beeswax.

1. Will bees on the side of a hill rob those below, say about 50 feet lower, and about 400 feet apart?

How can I make old comb into beeswax?

MAINE.

ANSWERS.—1. Such location would make no difference in the matter of robbing. Bees are just as likely to rob those below. Other conditions than those of position are responsible for starting robbing. A queenless or very weak colony is likely to be a victim, and the case is aggravated if there is too large an entrance, or if the appetites of the robbers are whetted by having combs or honey exposed so as to give them a taste.

2. A good solar extractor is perhaps the best thing. You may have something to act much in the same way by having an old dripping-pan and a cook-stove. Split open one corner of the dripping-pan, and put it in the oven of the cook-stove, with the split corner projecting out. A little stone, or something of the kind, should be put under the end of the dripping-pan that is inside, so as to make the wax run toward the split corner. Of course, the pieces of comb must be laid in the dripping-pan, and the door of the oven must be left open. Whether you use the dripping-pan or the solar wax-extractor, if you pile on a lot of pieces of old comb you will find that the cocoons of the old comb will act a little like a sponge, and will be filled with wax that you will not get. There will be less waste in this way if you put in your pan only a single thickness of comb at a time. A good way is to soak the combs thoroughly in water before putting them in the pan. Then break them up and pile on what you like. The cocoons being already filled with water can not become filled with wax as they would if dry. A dish must be set on the floor to catch the wax as it drops from the pan, and it is well to have in the bottom of this outside vessel a little hot water.

GENERAL ITEMS

Wintering Well—Prospects Good.

Bees are wintering well, while early snow preceded by soaking rains blanketed the best start of white clover we have had for several years. The prospects so far are not to be complained of.

H. G. ACKLIN.
Ramsey Co., Minn., Jan. 10.

The "Nameless" Bee Disease.

The past year has been a poor one for bees, but I think mine gathered enough to carry them thru the winter.

I had a little experience with the "Nameless" bee-disease last fall. One colony was so bad that it could not defend itself from robbers. I covered the hive with a sheet at night, and exchanged the stands, and the next spring there was no sign of the disease left, and last fall they seemed to be as good as any colony I have.

CHAS. BLACKBURN.
Buchanan Co., Iowa, Dec. 31.

A Bee-Keepers' Institute.

The bee-keepers' institute was held at Johnstown, N. Y., Dec. 18, 1900, and a goodly number of bee-keepers were present.

The meeting was called to order by one of the State bee-inspectors, Chas. Stewart. Mr. W. Z. Hutchinson delivered an able address on "The Use and Abuse of Comb Foundation," and an interesting discussion followed.

At the close of this meeting an association was organized for Fulton and Montgomery counties, and the following officers were elected: President, J. W. Hoffman; 1st Vice-President, G. H. Adams; 2d Vice-President, E. W. Rean; 3d Vice-President, G. W. Haines; Secretary, T. I. Dugdale, West Galway, N. Y.; and Treasurer, D. E. Floyd. A number of members were received, and the next meeting will be at Fondra, N. Y., the first Tuesday in May.

G. W. HAINES.
Fulton Co., N. Y., Jan. 7.

Managing Bees—Carniolans.

I ran three of my colonies last season on a different plan from what I have been doing, and got \$45 worth of No. 1 comb honey from the three; and I am going to try the same thing the coming season, and if it comes out all right I will give you the plan.

I had a fine colony of Carniolans which had one super on early in May; I was thinking of slipping another one under it, and before I got ready to do so a swarm issued and went some distance before it settled. After it clustered I hived it and brought it home. It was a powerful swarm. In a day or two I was out in the apiary and noticed a stream of bees going in and out at this new colony. I did not at first think much about it, because I knew it was a very large swarm, and thought they were hustling, and concluded that these Carniolans were dandies. When I finished my work I went over to look

BULL-STRONG!

...PIG-TIGHT...

An Illinois farmer said that after harvest he had fully 200 bushels of loose oats on the ground that he could not secure any benefit from, because the fence around the field would not turn the pigs. Figure the loss for yourself. He also said, all this would have been saved if he had used the Kitzelman Woven Wire Coiled Spring Fence, and the value would have gone a long way towards paying cost of the fence.

With the **Duplex Machine** any farmer can make it himself at the actual cost of the wire. Catalogs free for the asking.

KITZELMAN BROS.
Box 201, Muncie, Ind.

at them. I had placed them about 100 feet from the parent colony, and I noticed that instead of going to the fields the bees were going in a circle to the parent hive. I look into the parent hive and found that the swarm had taken all the honey from that hive and stored it in their own in the old combs I had given them. I let them alone, and on the fourth day all was quiet. Before fall the parent colony had rallied, it came thru the winter all right, and the next spring I sold it for \$9.00. I secured a fine crop of honey from the new colony that season.

JOHN W. BAUCKMAN.

Fairfax Co., Va., Jan. 7.

Not a Successful Bee-Year.

The past year was not a very successful one with bees in this part of the country. They did almost nothing, and stored so little surplus that we may as well say that the crop was a failure. They were so light in winter stores that I had to do a great deal of feeding. They may have enough to carry them thru till next spring, and I may have to feed again. White clover failed to yield any nectar, but we look for better things the coming season.

Don't forget to send us the old American Bee Journal, for if the season was poor I think I can't get along without it, so keep it moving along.

C. H. VOIGT.

Kewaunee Co., Wis., Jan. 1.

Not Much of a "Greenhorn."

We secured about half a honey-crop here last season.

I began keeping bees in the fall of 1895, and last spring I had 31 colonies, spring count, which I valued at \$4.00 per colony, which would make \$124 invested; I then put in \$15 worth of foundation, paid \$4.00 for help, and

Langstroth on... The Honey-Bee

Revised by Dadant—1899 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

GEORGE W. YORK & CO.

118 Michigan Street, CHICAGO, ILL.

BEE-KEEPERS!

Owing to my health, I am compelled to abandon the manufacture of the **GOLDEN COMBINATION HIVE**, and bee-keepers wishing a perfect sample hive, complete, will do well to order soon, as my large lot on hand will soon be exhausted. Write for prices and instructions, free.

DOES THE WORK BETTER THAN HENS.

OUR INCUBATORS

are scientifically perfect, a 200 egg hatching more chicks than 20 hens and at a time when sitters are hard to get. As money makers, no apparatus will equal a Successful Hatcher. We are the largest exclusive manufacturers of standard incubators and brooders. Send 6 cents for our 104-page Catalogue, printed in 5 languages. Address: DES MOINES INCUBATOR CO., Box 78 DES MOINES, IOWA

Please mention Bee Journal when writing.

WE PAY THE FREIGHT.

INVESTIGATE BEFORE YOU BUY.

We want our customers to be perfectly satisfied before they spend the money. Investigate the claims of all incubators and brooders. We believe we will win.

SURE HATCH INCUBATORS

AND COMMON SENSE FOLDING BROODERS are giving better satisfaction than any other article and are simple, sensible and sure. They are built for busy people, who haven't time to fuss and bother. Our catalogue is FREE. We don't ask you to pay for it. Don't work us again.

SURE HATCH INCUBATOR COMPANY, CLAY CENTER, NEBRASKA.

Please mention Bee Journal when writing.

Four Celluloid Queen-Buttons Free

AS A PREMIUM

For sending us ONE NEW SUBSCRIBER to the American Bee Journal for three months with 30 cents, we will mail you FOUR of these pretty buttons for wearing on the coat-lapel. (You can wear one and give the others to the children.) The queen has a golden tinge.

This offer is made only to our present regular subscribers.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one (of the buttons) as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate, it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

Prices of Buttons alone, postpaid: One button, 8 cts.; 2 buttons, 6 cts. each; 5 or more, 5 cts. each. (Stamps taken.) Address,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

Draper Publishing and Supply Co.—There appears elsewhere in this issue the ad. of the Draper Publishing & Supply Company, Chicago, which we hope every reader of this paper will see. These people have 3 high-class papers, each occupying a separate and distinct field—Dairy and Creamery, Wool Markets and Sheep, and Commercial Poultry, all semi-monthlies. The subscription price of each is only 50 cents a year, and valuable premiums are offered. Those who are in a position to secure subscriptions will receive liberal terms on application. Write the Draper Publishing and Supply Company to-day for sample copies, and tell them you saw their advertisement in the American Bee Journal.

GINSENG 810, in plants produce \$4.00 to 10 in 10 cents. Book telling how to grow it. At Lakeside Ginseng Gardens, Amber, N.Y.

workt eight days myself. Counting my work worth \$2.50 per day would be \$20, hence my spring valuation and all expense to date would be \$163.

My bees increase 10 colonies, which at \$4.00 per colony would be worth \$40; I extracted 22 cases of honey, 120 pounds per case, or 2,640 pounds, which sold at 6 cents per pound would bring \$158.40. This with the increase worth \$40 makes a total of \$198.40, the income on a \$163 investment, allowing myself \$2.50 per day for the time I work. How is that for a greenhorn?

C. E. STEVENS.

San Diego Co., Calif., Jan. 2.

Did Fairly Well—Paper-Bag Feeder.

My bees did fairly well the forepart of the summer, but the fall crop of honey was an entire failure on account of the dry weather, tho all had a good supply for winter stores. One colony that did not swarm stored 54 pounds of honey, besides having plenty for winter. The colonies that swarmed stored no surplus honey; I had \$11 worth in all. I sold one colony, and put 12 into winter quarters on the summer stands.

I do not quite understand Mr. Kernan's article (page 606, 1900) on paper-bag feeders, and wish he would be kind enough to give his plan a little more completely, in the Bee Journal. Does he make the pin-holes on the top of the sack, or where? and does he make many of them? I was quite favorably impressed with the plan, as I have so much feeding to do, and no one to help me.

MRS. SARAH J. GRIFFITH.

Cumberland Co., N. J., Jan. 2.

Report For the Season of 1900.

I had 120 colonies, spring count; I divided the strong colonies and now have 165 in fair condition, I hope. I have done nothing with them since July, but manzanita is beginning to bloom and I must overhaul them at once.

The amount realized on honey the past season averaged about \$2.00 per colony. It has been higher than I have ever seen it since I have kept bees.

C. W. KERLIN.

Monterey Co., Cal. Jan. 1.

"Reducing the Swarming Habit."

My bees are in fine condition; the weather could not be better for them to clean house, and have a good flight.

On page 819 (1900) I noticed an editorial on "Reducing the Swarming Habit." I can agree with Mr. Lathrop and Mr. McNay (and many other bee-keepers can do likewise), in saying that by careful attention on the part of the bee-keeper swarming can be discouraged, but I can not agree with them in saying that bees can be reared that will be non-swarmers, for this reason:

I have been keeping bees—tho not continuously—since 1883. I sold out in Nov., 1897, but started again in the business in 1899 with 7 colonies, which I have increased to 13; in all these years I have had but two natural swarms. When I sold out in 1897 one bee-keeper bought 4 colonies that I had had for 6 years—one colony with a 3-year-old queen, two colonies with two-year-old queens, and one colony with a queen of July, 1897—and in all that time they

had never swarmed under my treatment. But in July, 1898, this bee-keeper informed me that 2 of the 4 colonies had swarmed and that from one of them an after-swarm had issued.

I have bought, and received in other ways, strains of bees from the apiaries of some of our most noted bee-keepers; some of them have not had the opportunity to swarm, and others I have succeeded in preventing from it.

Personally, I do not believe it is to the best interests of the bee-keeper to discourage his bees from natural swarming. Better results will be secured if the bees that are gentle are allowed to increase in the natural way; but bees that have cross dispositions ought to be prevented from swarming, as it acts very much like taking the horns off of the stubborn ox and putting it on a level with the lamb.

DANA H. GRAHAM,
Lancaster Co., Pa., Dec. 31.

Seem To Be Wintering Well.

Bees are flying to-day, and seem to be wintering fairly well.

ELVERT W. HAAG,
Stark Co., Ohio, Jan. 11.

Poor Season—The Bee Journal.

The past has been the poorest season for honey in this locality in many years. I secured 26 good colonies in two-story 10-frame hives, and they nearly filled the supers.

I would not think of getting along without the Bee Journal. I have read and reread three of the standard bee-books during the last year, and am well satisfied that the copies of the Journal for the past two years are worth more to a beginner than all of these books put together. The textbooks are all excellent, and well fill the place for which they are intended, but the amount of original thought and experience which we get from conventions and otherwise thru the Journal are above everything else.

S. N. SALSBURY,
Cochise Co., Ariz., Jan. 1.

Smallest Crop in Years.

We had the smallest honey-crop in this county the past season that we have had in a number of years; in many apiaries the bees stored no surplus. The goldenrod and wild aster yielded no nectar, and the oldest bee-keepers say that this never happened before in this "neck of the woods."

Our bees had their last flight Nov. 6th, and will probably be in winter quarters until April 1st. Many colonies are very light in stores. We winter them in the cellar, and they are now in splendid condition.

We had plenty of warm rains late in the fall, early snows, and no frost is in the ground. The clovers are doing well, and we are sure of a big crop next season.

WM. ROBINSON,
Barron Co., Wis., Jan. 7.

A Canvassing Experience.

If every one could get as much fun out of canvassing for new subscribers as I have, I think you would have plenty of agents. I called on one old gentleman, and, after showing him

the Bee Journal, I told him that if he expected to be successful in keeping bees he should keep posted and read a bright, wide-awake journal. His reply was, "Look here, Donaldson, I kept bees before you were born, and I have forgotten more about them than you know. I tell you it's all luck." I then ask him how it happened that my bees came thru the winter all right when bee-keepers around me lost all that they had. He replied, "You were lucky; that's all there is to it." I thought my next question would "floor" him, so I ask him how he accounted for the fact that I secured a good honey-crop when others did not get any. He replied, "I tell you it's all luck; you'll see, your luck will change, too. I had just as good bees as you have, and the first thing I knew they were all gone. The worms ate them all up." I concluded he was a hopeless case.

J. M. DONALDSON,
Worcester Co., Mass., Jan. 1.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Jan. 19.—Honey is selling slowly; this applies to all grades with the exception of white clover and basswood comb honey, which sells readily at 10c providing it grades No. 1 or better. All other kinds of white comb honey sell at from 14c to 15c, and candied white comb at from 8c to 10c; travel-stained and off-grades of comb, 13c to 14c; amber, 12c to 13c; amber extracted, 7c to 7 1/2c; dark and buckwheat comb honey, 6c to 10c. Extracted white, 7c to 8c; basswood and white clover bringing the outside prices; buckwheat and other grades, 6c to 6 1/2c. Beeswax, 25c. R. A. BURNETT & Co.

KANSAS CITY, Dec. 21.—Honey market firm, demand steady. Fancy white comb, 24-section case, \$3.50 to \$3.75; 12-section case, \$1.90 to \$2.00; amber, case, \$3.00 to \$3.25. Extracted white, 8c to 8 1/2c; supply fair; receipts and demand good. Beeswax, 22c to 23c. Demand fair.

W. R. CROMWELL PRODUCE CO.,
Successors to C. C. Clemons & Co.

BUFFALO, Jan. 17.—All kinds of honey are so quiet it is difficult to make a sale. Occasionally some sells, fancy 14c to 15c; few, 10c; choice and No. 1, 12c to 13c; few, 14c; but dark, 9c to 10c, and all kinds in liberal supply; some may have to be reconditioned. Extracted, 7c to 8c, and not wanted in Buffalo. Beeswax, 22c to 27c.

BATTENSON & Co.

ALBANY, N. Y., Jan. 18.—Honey market is dull on all grades now, with light stock and light demand. White comb in good condition, not candied, 15c to 16c; mixt, 13c to 14c; buckwheat, 12c to 12 1/2c; mixt, 11c to 11 1/2c. Extracted, white, 8c to 8 1/2c; mixt, 6c to 6 1/2c; dark, 5c to 5 1/2c.

H. R. WRIGHT.

BOSTON, Jan. 18.—Fancy No. 1 white in cartons, 17c; A No. 1, 16c; No. 1, 15c to 16c, with a fairly good demand. Absolutely no call for dark honey this year. Extracted, white, 8c to 8 1/2c; light amber, 7 1/2c to 8c. Beeswax, 27c.

BLAKE, SCOTT & LEE.

CINCINNATI, Jan. 16.—Market very quiet. No change in prices. Fancy white comb sells for 10c. Extracted, dark, sells for 5 1/2c, and better grades bring 6c to 7 1/2c. Fancy white table honey brings from 8 1/2c to 9c.

C. H. W. WEBER.

NEW YORK, Dec. 23.—Fancy white, 15c to 16c; No. 1 white, 14c to 15c; No. 2 white, 12c to 13c; amber, 12c; buckwheat, 10c to 11c. Extracted in fairly good demand at 7 1/2c to 8c for white, and 7c for amber; off grades and Southern in barrels at from 6 1/2c to 7c per gallon, according to quality. Not much demand for extracted honey at yet. Some light selling at 5 1/2c to 6c. Beeswax firm at 28 cents.

Demand continues good for comb honey; supply fairly good. Extracted in fair demand and enough supply to meet requirements.

HILDRETH & SEGELKEN.

DETROIT, Jan. 19.—Fancy white comb, 15c to 16c; No. 1, 13c to 14c; dark and amber, 12c to 13c. Extracted, white, 7c to 7 1/2c; amber and dark, 6c to 6 1/2c. Beeswax, 26c to 27c. M. H. HUNT & SON.

SAN FRANCISCO, Jan. 9.—White comb 13c to 14c; amber, 11c to 12c; dark, 8c to 9c. Extracted, white, 7 1/2c to 8c; light amber, 6c to 7c; amber, 5c to 6c. Beeswax, 26c to 27c.

Stocks of all descriptions are light, and values are being as a rule well maintained at the quoted range. Firmness is naturally most pronounced on lid amber and dark, while the honey, the latter being in very scanty supply.

HONEY MARKET.—We may have a customer within a short distance of you who wants to mount honey or beeswax. We are in close touch with all the markets; therefore write us regarding your crop, stating quantity, quality, and lowest cash price. References to our Bank here for any business man in this city.

CHAS. DADANT & SON, Hamilton, Hancock Co., Ill.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The holsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise it tends to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00). We will club the Novelty Knife and the Bee Journal for one year, both for \$1.50.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

AMERICAN BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., JANUARY 31, 1901.

FORTY-FIRST YEAR
No. 5.

WEEKLY

*Apiary of Mr. and Mrs. James R. Conklin,
of Cayuga Co., N. Y.*

See page 72.]

PUBLISHED WEEKLY BY

GEORGE W. YORK & CO.

118 Michigan St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50c a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Decm" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

Reformed Spelling.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th 1899 Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equip, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
118 Michigan Street, CHICAGO, ILL.ALFALFA
OR
BASSWOOD

THE BEST WHITE

Extracted Honey

ALL IN 60-POUND TIN CANS.

ALFALFA
HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD
HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

We have a good stock of the fine WHITE ALFALFA and WHITE BASSWOOD EXTRACTED HONEY that we can ship by return freight. Most bee-keepers must have sold all their last year's crop long before now, and will be ready to get more with which to supply their customers. All who have had any acquaintance with the above-named honeys know how good they are. Why not order at once, and keep your trade supplied?

Prices of Either Alfalfa or Basswood Honey:

(For the purpose of selling again.)

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are boxt. This is all

Absolutely Pure Bees' Honey,

The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:

I've just sampled the honey you sent, and it's prime. Thank you. I feel that I'm something of a heretic, to sell several thousand pounds of honey of my own production and then buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drink, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honeys of more market flavor, according to my taste. C. C. MILLER, McHenry Co., Ill.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 118 Michigan St., Chicago, Ill.

26 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 26 cents a pound—CASH—for best, yellow, upon its receipt, or 28 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

No. 5.

* Editorial. *

Removal Notice.

Beginning Feb. 1st, our place of business will be at

144 & 146 Erie Street,

instead of 118 Michigan Street. Our correspondents, and customers who are in the habit of calling at our office, will please note this change in location.

After our loss and general disturbance here, caused by the fire in this building on Jan. 1st, we concluded it would be best for us to seek another location. We had little trouble in finding what we think will suit us exactly.

The new place is on the first or ground floor—so there will be no more stairs to climb, as is the case here. Also, there will be no need for a freight elevator at the rear, on which we have had to load and unload all our goods the past eight years. This will save considerable handling. We will have a larger floor space at our new location, so we will be able to have everything on one floor, instead of on two as has been the case here a part of the time.

Our new office—144 & 146 Erie Street—is just a few short city blocks—(about 100 rods)—due north of the Chicago & Northwestern Railway Passenger Station on Wells Street. We will be just about midway between Wells Street and Franklin Street on Erie Street.

We think now none of our friends who come to the city will experience any difficulty in finding us.

Come and see us in our new business home—after Feb. 1st. GEORGE W. YORK & Co.

Bees and Fruit.—The editor of Green's Fruit-Growing—Mr. C. A. Green—offers the following testimonial to the value of bees to the growers of fruit:

"But as regards bees injuring fruit, there is no doubt in my mind that this is a fallacy which should be corrected thru the agricultural and horticultural press thruout the country. Make it plain to all growers that bees do not injure fruit, but that they are in reality the friends of the fruit-growers."

We have no doubt that those fruit-growers who have studied the subject will agree with Mr. Green. We believe that most of the opposition that has shown itself on the part of fruit-growers in the past has been a result of ignorance, or perhaps a desire to injure bee-keeping. We are quite certain that at the last analysis it will be shown that bees are of the greatest possible value to all growers of

fruit, and that when they endeavor to destroy the bees or prohibit bee-keeping they are simply "killing the goose that lays the golden egg" for them. The trouble will likely be that most of the opposition will discover their error too late.

We notice in Gleanings in Bee-Culture that it is proposed to hold a joint meeting of bee-keepers and fruit-growers during the Pan-American Exposition next summer at Buffalo, N. Y.—at least one day of a joint session of the representatives of the two interests mentioned. We believe this should be a good thing, and every endeavor should be put forth to bring it about. Of course, it is just possible that the National Bee-Keepers' Association may hold its meeting at Buffalo, and likely, if such should be decided upon, the joint meeting referred to could be arranged all right. It will be helpful if the representatives of the two pursuits can come face to face, and discuss questions which are of so much mutual importance. We should be pleased to be able to announce soon that an arrangement has been made whereby the bee-keepers and fruit-growers can have the proposed joint meeting at the Pan-American. It would go far, we think, toward settling the question permanently in regard to the value of bees to fruit.

Bees on Shares.—To the often recurring and always troublesome question as to the right share of products to be given by the owner to the keeper of bees, the editor of the Australasian Bee-Keeper replies in the following sensible manner:

"Of all matters connected with bee-keeping, that of engaging another to look after the bees on shares is the most difficult to arrange satisfactorily, and I really think it is impossible to have an understanding on all points, there are so many things to be considered. Where the apiarist does the work for a share of the products, he should be allowed what might seem a rather large proportion, for he has to take all risks of the season, and the market rate, provide his own time, etc. No, I would rather discourage any such arrangement, knowing it to be unsatisfactory. I once had an apiary on similar terms, and the two were able to satisfy each other, there were so many points crop't up that unless each made up his mind to be liberal and not exacting, a dispute would have arisen, and it seemed as if each party must be prepared to decide all points in favor of the other to settle up and remain good friends. If you wish to engage a man for the most satisfactory arrangement is to pay him wages and retain all products, when you can dictate the amount of increase to have, and how the apiary should be worked. You may think that a man has an interest in the concern he will be more attentive to his work and do better; such reasoning is very good, and the one way to make such an arrangement is to pay the producer a price per pound, or per tin, for the honey he produces. The wax product would have to be arranged; if wax is paid for in the same way there

would be an inducement to melt up combs, and yet if wax is not paid for no attention may be paid to its saving, and the apiary made dirty with wax-scrap and bee-moth.

"To engage a man for one season on these terms he would not permit of increase, and may rather decrease the number of colonies at the close of the season to get the greatest amount of honey; also, unless each hive is arranged to contain a certain weight of honey they would be extracted too close for winter. This was my experience under a similar arrangement, and on the whole the only satisfactory arrangement is to pay wages and retain all rights and take all risks; then if the apiarist is not doing his work satisfactorily he can be dismissed not so under any other arrangement."

The Utter vs. Utter Case.—Dr. Miller, in a Stray Straw in Gleanings in Bee-Culture, has this to say about the double-Utter case recently mentioned in these columns:

"That Utter-Utter decision is alone worth more than all the money that has been put into the National Bee-Keepers' Association's treasury. So was the adulteration fight in Chicago. Now, my friends who are not yet members, don't you think you can afford to put in a dollar each to help on the good work? A lot more good can be done by the Association if it has a full treasury."

Editor Root, in commenting on the above paragraph, writes thus:

"In my humble judgment the decision of the Utter trial was worth more—vastly more—than that of the celebrated Arkadelphia case, important as that was. If the decision in the first-named had been against us, and left there, bee-keeping might have been wiped out of many fruit sections of the United States. The Arkadelphia case related only to bees in towns and villages; and if that had gone against us it would have wiped bee-keeping out of the great centers of population only, but would not have affected it in the least in the great acres of country half a mile and more from those centers. Why, it seems to me that the results of the Utter trial are worth thousands and thousands of dollars. If the National Bee-Keepers' Union, the United States Bee-Keepers' Union, or the North American Bee-Keepers' Association, now all merged into one, had never done any more, we could still feel that the money that has been put into the several treasuries was well invested."

We agree most heartily with all the foregoing. Of course, there are many bee-keepers who think that they do not make a sufficient business of bee-keeping for it to be worth while for them to join the National Association. We think, however, that they are making a big mistake. No one can tell just when he will have to meet the same kind of opposition as did Mr. Utter, the bee-keeper. It pays to be prepared in advance for any such attack. But even if it were unnecessary for you to defend yourself, you would have the satisfaction of knowing that by joining the Association you were doing good by helping others who are unfortunate enough to be compelled to defend themselves against envious or

ignorant neighbors. This writer has been a member of the Association for nearly 10 years, and has never had to call upon it for any help, and never expects the time to come when it will be necessary for him to call for such aid. However, he would not think of being outside of the Association, for, in view of such good work as it already has done for bee-keepers, he feels that it is a very little thing for him to pay his \$1.00 a year to help.

Instead of a membership of less than 600 there ought to be at least 6,000 bee-keepers who have paid their annual dues to advance the interests of the pursuit in which they are engaged. There are many lines of work that could be pushed if the officers of the Association had the means to undertake it. But we have always felt that even a larger membership would of itself be a great influence; if, when an attempt is made to secure the passage of a law against foul brood or spraying fruit-trees, those working for the passage of such law could say that the National Bee-Keepers' Association with its 6,000 membership was unanimously in favor of such laws, it would go far, we think, towards securing the enactment of such measures. So long as only a few of the thousands of bee-keepers in this country deem it of sufficient importance to belong to their National organization, we can hardly blame legislators for paying scarcely any attention to any resolutions or suggestions that might come thru the Association. In numbers, as well as in a full treasury, is their strength. It is true the full treasury is very necessary, but the best way to secure that desideratum is to get a larger membership. More money will always follow increased membership.

Not being an officer of the Association we feel very free to speak in its favor, and do all we can to get others to join and send their membership dues to General Manager Eugene Secor, of Forest City, Iowa. However, as we have often said before, if it is more convenient for any one to send the dues to this office we will be glad to receive it and forward to Mr. Secor, who will then mail individual receipts.

"The Uncapping Fork" continues to be vaunted in the German bee-journals as superior to an uncapping-knife. It is made with adjustable forks or needles, so that if one is broken it may be replaced. Price, with extra needles, 33 cents." So says a Stray Straw in *Gleanings in Bee-Culture*. We have seen one of the uncapping forks referred to, in the apiary of Mr. L. Kreutzinger, of this county. We do not know whether he has tried to use it, as he works mainly for comb honey. We hardly think that it could take the place of the uncapping-knife in this country.

In Love with Your Business. In one of our agricultural exchanges we read this recently:

"The successful farmers are the ones who are in love with their business."

"In love with their business." That's it. That's the secret of the truest success. You may not become rich while following a certain honorable business. You may not equal in many ways your competitor's ability to get ahead. But if you love your work there is good prospect of the best success.

We know some men who are "dead in

love" with their work. If it were not so they would turn their attention to something else, for they are not getting rich in their present business. But they are successful, nevertheless.

It is the same way with bee-keeping. Seest thou a man or woman in love with bees and their care, surely such will succeed, for they will persist until success is compelled to be theirs.

The young man who is truly "in love" never gives up the struggle until the young lady is won—or until he finds out the reason why he fails of success. The same spirit of determination should fire the heart of every man who would win success in any line of honest effort.

Weekly Budget

THE WISCONSIN CONVENTION will be held at Madison next Tuesday and Wednesday, Feb. 5th and 6th, in the State capital building. A portion of the interesting program is as follows:

President's Address, by N. E. France; Cellular vs. Outdoor Wintering, by A. P. Miner; Outlook for a Bee-Keepers' Exhibit at the Pan-American Exposition in 1901, by E. D. Ochsner; Honey Exchange, by C. A. Hatch; How to Maintain Present Prices of Honey in the Event of a Good Honey Crop, by Harry Lathrop; Short Cuts in Extracting, by Frank Minick; Discussion of Laws Pertaining to Foul Brood, by N. E. France; and Mrs. Evans and Mrs. Towle will each present a paper on subjects of their own selection.

The secretary, Miss Ada L. Pickard, in her announcement, says:

Many of the prominent and experienced bee-keepers will be present.

E. R. Root, editor of *Gleanings in Bee-Culture*, will present his stereotyped views on the evening of Feb. 5th. These we know to be highly entertaining as well as instructive, and to be appreciated they must be seen. Since Mr. Root presented these at the National Convention he has obtained many new slides, which will prove to be instructive and interesting to fruit-growers, as well as to bee-keepers.

A general discussion will follow each topic, and a free use of the question-box and answers will be a prominent and valuable feature.

Excursion rates, within 200 miles of Madison, one and one-third fare for the round trip, ticket purchase Feb. 4th, 5th or 6th good to Feb. 9th. Tickets in Wisconsin, over 200 miles from Madison, same rate, if purchased Feb. 4th, good to Feb. 9th.

Editor W. Z. Hutchinson, of the *Bee-Keepers' Review*, as well as the editor of the *American Bee Journal*, expect to be present also. We are anticipating a good meeting. Wisconsin bee-keepers should turn out in full force.

MR. O. O. POPPLETON, it seems, has been receiving considerable notoriety recently in several of the bee-papers. About two months ago we received his photograph, expecting to use it in the *Bee Journal* very soon after, but before we were able to do so we found that the *American Bee-Keeper* had also decided to present his picture, which appeared in the December issue of that paper. Then, just

after making up our forms of the last week's *Bee Journal*, in which appeared Mr. Poppleton's picture, we received *Gleanings in Bee-Culture*, and discovered it there also. So it seems that at least three of the bee-papers had been planning to show Mr. Poppleton to their readers. It is all right, as there is no one in all the ranks of bee-keepers whom they would be more pleased to see and read about.

It was Mr. A. I. Root who said to his son E. R. Root, when he (A. I.) had the editorial management of *Gleanings in Bee-Culture*, "Whenever you see anything from that man Poppleton just hand it right in to the printer. It is *always* good. He is sound and practical." Editor E. R. Root says he has found his father's statement concerning Mr. Poppleton to be literally true.

Mr. Poppleton, as is known by most of the older readers of bee-literature, uses what is called the "Long-Ideal" hive, the frames being 12 inches square, and from 20 to 24 frames in each hive. These frames are all used in the brood-chamber, and, of course, are run entirely for extracted honey. Mr. Root says:

"Mr. Poppleton himself believes that the hive first devised by Langstroth 50 years ago has not been improved upon so far as shape and proportion of frames are concerned, for the production of *comb* honey. But the production of *extracted* honey is so different he thinks it is doubtful if the same style of hive and frame can be best for both."

MR. CHAS. BECKER, as well as other apianarian exhibitors at fairs, hear some queer remarks made by visitors who see the exhibits of honey and bee-supplies. At the Illinois fair last fall an old couple were gazing at Mr. Becker's large exhibit of bottled extracted honey. The old gentleman said to the old lady:

"What is that along there in them bottles?"

"I don't know unless it is an advertisement for a drug-store," replied the lady.

Mr. Becker is a very sweet "druggist."

On another occasion some spectators were strolling along and came to the honey-extractor. One of the company upon enquiring what it was, received this wise answer from another visitor:

"Why, they put the bees in there, and squeeze out the honey!"

And yet, some of us are just as ignorant about certain things as were the people referred to in the foregoing concerning common apianarian matters.

MR. H. G. OSBURN, writing to *Gleanings in Bee-Culture*, from Cuba, Oct. 10, 1900, after living there 12 years, advises any one contemplating bee-keeping in that country, to stay at home unless one can first go there and learn the difficulties to be encountered, and how best to meet them; also as to insects which delight to feast on "the rich red blood of the new comer, the very best stimulant for a good appetite." One year he extracted 15,000 pounds of honey from 600 colonies in five months.

Editor Root wisely says: "No one should ever think of 'pulling up stakes,' taking his all, and changing everything in a move to a new locality, much less go to a climate that is essentially different from the one in which he has been brought up."

Contributed Articles.

The Bee-keeper and the Bee-Supply Dealer.

A Colorado subscriber wrote us as follows Oct. 16, 1900, and we referred his letter to several bee-supply dealers requesting their opinion on the subject:

TO THE AMERICAN BEE JOURNAL:—

I want to purchase supplies needed for 250 colonies of bees. I don't know where to buy, for the reason that the business must be transacted by mail, and the purchase made at a factory some hundreds of miles distant. One bee-keeping neighbor needs a larger lot than I do, so of course we shall join in getting a car-load direct from the factory.

We should like to see the goods, check the invoice, and verify the measurements or other qualities, of the different goods, then pay our money on the spot. I object downright to paying for a large bill of goods that I have never seen. But I can't help myself. When the goods are manufactured, then counted and shipped, I am not represented. My money passes beyond my control, and I am helpless.

I know all the current answers to my objection; but the answers do not satisfy. The seller is honorable; that does not meet the case. The shipping-clerk is careful; that does me no good after an error is made. An error in counting can be corrected, and always is, if it amounts to much; but the error of the man at the saw, if his spoiled goods get shipped, is never corrected. We get softly-worded apologies, but these do not meet the requirement.

In making a rule of business to protect the seller absolutely, we have left the buyer absolutely unprotected. Cash in advance is perfect protection to the seller, but it is rank injustice to the buyer. Cash on delivery of goods, duly examined, checked out, and verified, is right.

Now, I submit that the bee-keepers, supply dealers, and editors ought to aggregate brains enough to make a rule of business that will protect both buyer and seller. Let us try the problem, at any rate. Will not the sellers of supplies lead the discussion?

COLORADO.

We have received the following responses to the above, from some of our advertisers:

DEAL WITH RESPONSIBLE FIRMS.

I do not consider the dilemma of our Colorado friend a serious one. If he wishes to purchase a car-load of supplies the goods will be figured to him at a very low price for the consideration of a quantity order with the cash. This is greatly in the favor of the purchaser. If he places his order with a strictly responsible house his goods will be guaranteed as ordered, and if, by accident, an error should be made it would be corrected without expense to him. As a rule, manufacturers and supply dealers are very honorable in their dealings, and if there are any that are not they must eventually drop out of the business.

After giving this subject much thought I can see but one explanation, and that is, to be certain to place the order with a responsible firm.

WALTER S. POWDER.

"COLORADO" TAKES A WRONG POSITION.

We note the copy of letter from your Colorado subscriber, which you enclose. We think he takes a wrong position in this matter, for this reason: If he wishes to purchase a car-load of goods, and can show as good financial standing in the business world as the manufacturer, then we would have no objection to sending him goods to be paid for when examined; but inasmuch as he is not in business, and not quoted in the commercial reference books, he could hardly expect that any one would trust him outright with a car-load of goods unless he could give satisfactory references.

We have never had any difficulty in satisfying our customers in the ultimate settlement of any disputed point, unless it may be with some one who has ordered only a few dollars worth of goods and is simply of that make-up that he would not be satisfied even if the whole amount of money he paid for the goods was returned to him.

Now we would suggest that if this party wishes to purchase a car-load of goods, and, as he says, he is willing to

pay cash, that he send the manufacturer one-third or one-half the cost of the goods, and deposit the balance in some bank to be paid to the manufacturer when the goods have been received and found satisfactory.

THE W. T. FALCONER MFG. CO.

NO RULE CAN BE LAID DOWN.

There is no rule that can be laid down in this matter, as the matter of credit to a strange purchaser by a dealer depends altogether upon the information that the dealer may or may not have obtained concerning the purchaser. If dealers were compelled to trust everybody, they would have to ask a much larger price for their goods to make up for dishonest customers, and the honest ones would evidently pay for the dishonest ones. Purchasers of large orders who understand the rules of business do not hesitate to furnish good references, and that secures them a credit, so they can see the goods before buying. On a small retail trade, however, it is not advisable to make credit, as it involves too large a correspondence and too much book-keeping. Between a fair dealer and a fair purchaser, there is no trouble once in a thousand purchases, because the dealer is always ready to take back incorrect goods and replace them, paying freight both ways. When there is trouble it is when the dealer is not fair, or the purchaser himself is unjust or gets angry at an error, instead of peaceably representing the mistake which needs correction. But as I said before, it does not happen once in a thousand deals that both parties get so angry that they can not agree on a satisfactory solution.

As we cut up very little lumber ourselves, but buy much of our stuff already cut from large mills, we are both a buyer and a seller in the goods furnished by "the man at the saw," and we must say that we find very little trouble in getting or giving satisfaction.

CHAS. DADANT & SON.

TRY TO DO AS YOU WOULD BE DONE BY.

Your Colorado correspondent is not so badly off as he imagines. In the first place it is not necessary or desirable even, for him to send his order hundreds of miles distant direct to the factory. He can place it with a large wholesale dealer in his own State, and receive just as good prices as tho he sent the order direct to the factory.

Again, if he is a reliable and responsible man, and can satisfy the one with whom he places his order of the fact, it is not necessary for him to pay for the goods until he sees them and is satisfied they are what he ordered. Neither the manufacturer nor the dealer wants to have any unfair advantage over his customers. The reason why the rule of "cash with order" has been adopted is not to take advantage of the buyer, but it is rather in his interest in preventing bad debts, thereby permitting of closer prices. If the manufacturer or dealer had the means at hand of ascertaining who were responsible and trustworthy and who were not, many people could be accommodated who, under the present conditions, find it less troublesome to send the amount with the order. We have the means at hand for men in the mercantile business; but not for farmers, professional men, etc., who make up the great majority of customers for bee-supplies.

Even if cash does accompany the order and it is placed with a responsible manufacturer or dealer, the buyer is not helpless if the order is not properly filled. Your subscriber seems to assume that the manufacturer would be more careful to avoid mistakes in filling the order if the payment was not to be made till after delivery and inspection, a proposition which is absurd from our point of view. We would have as much right to assume that the buyer would be more critical in his inspection, seeking for some basis as a claim for rebate, if he were allowed the privilege of inspection before settling for the goods. We have more faith in both classes, buyer and seller, than to ascribe to either such low standards.

Your correspondent says, "Errors of the man at the saw, if his spoil goods get shipped, are never corrected." That is a pretty sweeping statement which we think he would find it difficult to prove. We can cite him to numerous cases in our experience that would induce him to materially modify it. We always try to do as we would be done by, whether goods are paid for or not. Occasionally a man takes so unreasonable a position as to make it impossible to satisfy him; but we usually satisfy our customers.

THE A. I. ROOT CO.

THE HONEST SUFFER BECAUSE OF THE DISHONEST.

I have carefully considered the letter by "Colorado." It would appear that he has had bad work unloaded on him, and had to put up with it as it was. Has he ever dealt with firms that have given perfect satisfaction in quality and workmanship? If so, why has he not stood by them? This question is for customers in general.

The fact of the matter is, that a large proportion of bee-keepers are always looking for the cheapest, and they always get it. A customer of mine bought nothing of me last season until September. I find he had bought elsewhere at a less price, but admits that my goods were best, and again orders of me at my price, without making a single objection, as "Colorado" does.

Every supply dealer and manufacturer should be able to establish a character beyond any question, by the best of reference. I deal with hundreds of customers every year—it is an easy matter for every one of them to get my standing within a week, but it is an utter impossibility for me to find out the character and standing of all my customers. If every bee-keeper were honest and fair, then it would be perfectly safe and right for any reliable firm to submit goods for inspection before payment. But it is a melancholy fact that bee-keepers have their regular proportion of people that are dishonest, unfair, and cranky, as every dealer knows. We must protect ourselves against this class by "cash with the order," and the honest must suffer for it, until after having established a character with a firm, we sometimes make exceptions. But this does not protect us against losing customers, and we are forced to do the right thing to keep the business going.

Why should I, as a "manufacturer and dealer," "contribute any brains to make a general rule of business that will protect both buyer and seller?" Why should I contribute to make it perfectly safe for my customers to order of my competitor? If I have given them satisfaction and no cause to complain, let them keep on buying of me, and if they want to try the other man let them take their chance, and not ask me to make it safe for them to try him.

If it were a rule to ship goods on approval, we would be at the mercy of dishonest people. What is to hinder a man from ordering from several concerns and selecting the best as he sees it, and refuse the others on some pretext? We would never know, and if we did would have no redress. Or what protection would we have against a chronic crank and fault-finder?

Such conditions as Colorado complains of, while they are liable to happen to any firm, and in fact do happen, are exceptions. Where they are a rule, they will soon establish a reputation as being unreliable. For the few exceptions that happen to good firms, it is hardly worth considering a general rule as proposed.

Let each firm do business on a principle that will satisfy their customers. Let each make it a rule for themselves. Instead of forcing the dishonest and unreliable to do right, let it be a "survival of the fittest." Let honest and legitimate competition alone force a man to do right, and be careful and considerate in dealing with his customers. Let him command their confidence, and let them freely give it. It is only those that mistrust everybody else that we ever have any trouble with.

I have for a number of years shipped all of my honey to one firm, for the reason that I have confidence in their honesty, and I let good enough alone.

The only general rule should be with the publishers. Hold them responsible for the character of their advertisers. It is an easy thing for them to do, and they can afford it considering what we have to pay. Let it be understood, that the appearance of an advertisement is a guaranty for the character of the firm.

GUS DITTMER.

LATER.—I had thought that perhaps I had been a little too hard on "Colorado." I have just read the editorial on "A Dishonest Honey-Shipper," on page 69 (1900), and I am more than ever confirmed in the position I have taken. We must protect ourselves against that class of bee-keepers, and the honest must suffer in consequence. G. D.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Honey-Dew - Extracted-Honey Question.

BY C. P. DADANT.

I HAVE received the following to be answered in the American Bee Journal:

ME C. P. DADANT.—Would you be kind enough to answer a few questions on the production of extracted honey?

1. In our locality we have an occasional flow of the so-called "honey-dew." Is there any danger of this being carried up into the extracting-frames, or will it be used up for brood-rearing before the white clover honey-flow? The honey-dew flow comes in early spring when the oaks are leafing. What I want to know is, Will it injure the grade of the white clover honey?

2. How do you put your honey, as soon as extracted, into cans or into a tank?

3. How do you clean extracting-combs after the honey-flow is over?

4. Is it best to leave them on the hives from spring until fall?—CARROLL CO., ILL.

1. Honey-dew is harvested and carried into the supers just like any other crop. In the extracting supers, and when there is no other honey harvested at the same time, it is all right, for it can be taken out and sold separately. It is certainly not good honey, but it is a "sweet," and much better than no crop at all. In 1890 or 1891 (I do not remember which), we harvested some 30 barrels of almost pure honey-dew, and in fact there was little else. This was sold by us at five cents per pound for baking purposes, and I believe also for the use of tobaccoists. We have used it ourselves in wine-making and found it quite as efficient as any other grade of honey. But its taste, for consumption as honey, is not a recommendation. Some people call it "bug-juice," and seem to abhor it. Some of it, probably the bulk of it, is certainly a production of aphides, but undoubtedly also some honey-dew is an exudation from the tree, especially that which is gathered around the acorns.

The fact that honey-dew is the product of aphides should not condemn it for all purposes. If aphides are "bugs," so are bees; they are all insects, and the fact that one product is unpalatable does not make it entirely useless or worthless. And in the matter of edibles, much depends how we consider things. What we call cheese is called by the Chinese "rotten milk," but we think cheese a greater dainty than the young dogs that the Chinaman roasts as a delicacy.

One consolation is that honey-dew does not usually prove very plentiful in times of a great clover honey-flow. Then, the bees do not like it as well as clover honey, and they do not always gather it when there is a good flow of the better nectar. Yet there are times when clover and honey-dew are harvested together. This is unfortunate for the clover crop, for it does not take much of the poorer article to stain it in color, and to spoil the flavor. The only remedy is to sell the mixture at a lower price. But we must avoid keeping it for winter food, for there is not the slightest doubt that it is not as healthy as white honey, probably because it does not contain as much saccharine substance, or because it contains more foreign matter, which amounts to the same thing.

2. We have always practiced putting our honey, as soon as harvested, into barrels. Our reason for doing so is, that, with the large crops we harvest, tanks would be very cumbersome and very expensive. Then, we have never had any trouble with barrels, though we see that many people complain of them. It is probably because we have always taken pains to secure first-class, dry barrels, such as have been used for alcohol or syrups, that are usually coated with some sort of glue on the inside, which makes them honey-tight. Too many people imagine that they can take a leaky barrel and soak it with water, as they would for wine or cider, and make it do for honey. This is a grave error. Honey absorbs moisture to such an extent that it will readily "drink up" the water contained in the wood, and thus will dry up the wood and leave the barrel leaky as before. We found, at our expense, that if you take and melt a lot of honey, and put it while hot, into even a very sound barrel, the heat of the honey will dry up the wood enough to cause it to leak at once, when it would not have done so if cold honey had been put into it. We prefer barrels to cans because we can handle the honey and draw it off into any kind of a receptacle when ready to retail it.

But we do not wish to speak against the honey-tank. Any apiarist who has sufficient room and can secure a good, big tank can place the honey in this and probably have it continue to ripen, after it is harvested, if the tank is kept in a warm, dry place. Such a tank should be made of galvanized iron or heavy tin, and placed where the honey may

be drawn off thru a faucet without having to move the tank. For a crop of a few hundred, or even of a few thousand, pounds, this is certainly good. We sometimes have unripe honey, and I know that such honey would be benefited by standing in an open tank in hot weather. But if the crop is harvested at the right time, there is usually no need of artificial ripening. There are seasons when the weather is damp and the crop is so watery that it even ferments in the combs before harvesting. No amount of ripening will help such honey.

3. We always return the combs to the hives to clean them. If there is no honey in the fields at the time of extracting, we wait until evening to return the extracting supers, so that the bees may not be incited to rob. About sunset is a good time, and if any excitement prevails it dies out before any damage is done. The next morning all is quiet. In a good season, when the bees are still at work, the combs may be returned at once, that is, the combs of one hive, that have just been extracted, are exchanged for those of the next, and so on, till the end of the day.

We have tried keeping the combs over, from one year to another, without giving them back to be cleansed—they do not like it. They are sticky, and leak more or less; they attract mice and robber-bees, and the liquid honey that sticks to them is likely to sour. Then when spring comes, if we happen to put them on the hive during a day of short crop, we have some risks again from the excitement caused, and some danger of robbing.

4. Yes, if your colonies are strong, the combs are better off on the hives during the summer than in the honey-house or anywhere else. Even if there is no crop, the bees take care of them and neither mice nor moth can touch them. But we must not leave a lot of supers on a weak colony. That would be an error. Some judgment must be used in this as in any other thing. Let us always remember that successful bee-culture is made of many little details, and that the most careful man is also the most successful.

Queen-Rearing on a Roof—Feeders and Liquefying Granulated Honey.

BY JOHN R. SCHMIDT.

SO much has been said already about bee-keeping on a roof, and especially as this has been my subject quite often it is really becoming one of the "old chestnuts." It is about time this subject were buried, at least long enough to allow the readers to recover from the "too much of one thing" malady which creeps into our periodicals so often, not only in bee-literature, but in many others as well. For instance: Not long ago while talking to a photographer who has made a success of his profession, I chanced to ask him which is the best photographic journal publisher. Picking up one of the high-priced journals and turning to the frontispiece he said: "Here we have an example of composition and lighting that we buried 20 years

ago, and it is the same with many of the articles as well—the rethrasing of the same old things until we actually do not care to read them." Now this is just the trouble with articles written on bee-culture—the rethrasing of the same old things until the advanced readers will not read them.

The only excuse I have for bringing an old subject before the readers is, that it introduces something which heretofore to my knowledge has never been attempted on a large scale, viz: The rearing of queen-bees for the trade. The illustration herewith is a photograph of the C. H. W. Weber apiary again, and also shows a few of the nuclei used last season to accommodate some of the queens. It has been suggested that the only sure way to get queens purely mated is to establish an apiary on an island, away from other bees, and even to accomplish this desired result a desert was mentioned. Probably this led to the idea of going to the other extreme and rearing them on a roof in the city; anyhow, this has proven to be a capital idea, at least in this city, where house-top apiaries are few and far between. Mr. Weber tested this method of queen-rearing last season and found it to work well, his business having developed to such an extent that a move was necessary to the roof proper, about 20 feet higher, where more room and sunshine could be given the bees.

The same idea of having the hives under cover has been adhered to, as this is important when located on a high roof where the wind has full sweep without a break, over the house-tops. It would become a troublesome and often disastrous undertaking to winter hives of bees under any other method, but as it is here, each hive nestles up to the second story in a solid packing both winter and summer. A thing of no little importance has been added to these hives. That is, every one has a permanent Doolittle feeder on the north side of the broad-chamber, and manipulated entirely from the outside thru a 1/2-inch tin tube closed with a cork. The arrangement is so convenient that one may feed any desired amount of syrup at any and all times; even in the coldest days the bees may be fed with the same convenience and safety as in summer, the packing not being disturbed in the least. Just pull out the cork, insert a funnel, pour in the feed, replace the cork, and we're ready for the next hive. This is almost convenience itself, and as near being the perfect way to feed as anything could be.

Another thing, every one of the hives under cover has three queens in each—two young laying queens besides the old one—living peaceably, too. I believe this was considered impossible heretofore. Can't tell you now (by request) how it is done, but it is an accomplished fact—nothing theoretical about it.

LIQUEFYING GRANULATED HONEY.

The sale of liquid extracted honey is another specialty of Mr. Weber's, and to keep it in the liquid state is not an easy thing to accomplish, judging from the amount of granulated honey we see. This locality undoubtedly wants liquid extracted honey, and to make a success of the business we must give them what they want. Realizing this,

Mr. Weber has devised a liquefying-tank with a capacity of one barrel at a time. The honey-chamber is surrounded by a water-bath, and the water is heated by a gas stove of special design. The exact amount of water in the tank can be read from the outside upon an automatic register, and when the water is too low a turn or two of a small wheel admits the water thru a separate hydraulic connection for this tank. Should the water supply become too great it may be turned into a drain-pipe, and needs no further care. The temperature of the surrounding water is of great

Roof Apiary of Mr. C. H. W. Weber, Hamilton Co., Ohio.

importance, and to know to a degree just how hot the water really is, is accomplished by a thermometer on the outside which registers the exact temperature of the surrounding water in the tank. A glance at this will tell us just where we are "at" at all times, and there is no danger of overheating except thru carelessness. Any variation from the desired temperature is easily controlled by the perfect system of heating, and cold water supply. All this will be appreciated the more when it is said this tank is located in the store in full view of all customers and visitors, and its novel appearance excites much curiosity. The honey when reliquified is run into bottles, corked, and hermetically sealed while hot with a preparation which looks like beeswax, and something especially appropriate and pleasing when used for this purpose.

Is this tank a success? Well, I believe I can safely say it is. Two bottles of reliquified honey which I saw had been on ice constantly for three months, and after this long time did not show the least trace of granulation. If bottled honey will stand so severe a test as this there is no necessity for educating the people to eat granulated honey. I was told a tank like this does not cost over \$100, and it certainly would be a good investment for many. To see it one would think it cost a great deal more.

Such are a few of the good things Mr. Weber has thought out himself, and if he could be induced to describe them with his own pen I am sure he would put a few "wrinkles" into some of the most prolific writers.

Before closing I would like to say that some parts of this article may read like a puff for Mr. Weber. To all those who think it such, I would say that I write only hoping to give something new and practical to the readers, and if a person deserves credit for such a thing it is no more than right that he should be mentioned in connection with it.

Hamilton Co., Ohio.

The Conklin Apiary in Rhyme.

BY MRS. JAS. E. CONKLIN.

In the village of Moravia this apiary's found—
Just out behind the barn are the busy workers' round;
Bounded on the east by berries, and on the west by hens,
On the north by a vacant lot, a neighbor it defends.

The owner that's at work there, was born in '53;
He stayed on the farm with father until he married me,
We went to farming right away, instead of a wedding trip,
But he hankered so for honey that one-day he bought a "skip."

You all know what the fever is that one swarm brings to men—
Well, I guess the only remedy is to get some more of them.
Mistakes, experiments, and even death didn't break the fever up—
Still on it raged till cooled by drink from a successful cup.

We finally gave farming up, and to the village came,
But his appetite for honey is very much the same.
Bee-keeping sirs—and also wives—those both short and tall,
When passing thru this place we'll be glad to have you call.

Cayuga Co., N. Y., Dec. 19, 1900.

The "Bull-Dog Ant" of Florida in the Apiary.

BY PROF. A. J. COOK.

I HAVE been much interested in a correspondence with H. E. Hill, of Florida, regarding a large red ant of that State. Mr. Hill says he has not seen this species in Canada, Cuba, or in any section of the United States except Florida. These ants are very serious pests in the apiary, and their destructive habits make it imperative that the beekeeper give them special attention. Mr. Hill states that he has lost as many as 19 nuclei in a single week from these predatory ants. This is true notwithstanding that the nuclei were fastened on the trunks of palm-trees quite a distance from the ground. A further precaution was also taken of placing a girdle of cotton wadding saturated with carbolic acid around the tree above and below each nucleus.

Districts not cultivated are fairly alive with these ants. They burrow deep in the roots of old stumps, under logs or other pieces of wood, in the grass, between the walls of buildings, in wood-piles, in ventilated hive-covers, beneath the bottom-board of hives, in the vacant space of a contracted hive, between the shingles of old buildings, in rot-

ten portions of tall trees—in short, may be found in any place that affords them a harbor.

Mr. Hill has never counted them but believes that a colony may number two or three thousand ants. It is quite common, however, for a detachment of a few hundred to gather in any place affording a safe rendezvous. They are very ready to occupy any convenient harbor near the apiary. Hence the need of great vigilance on the part of the bee-keeper.

It is a curious fact that queenless colonies, or any colony in the apiary weak in numbers, are quick to be discovered by these marauders and are almost certain of attack and extinction. They always make their onslaught in the night-time; and even populous colonies not infrequently succumb to their attack.

I have long believed that ants are to the Arthropoda what man is among Vertebrates. Even the study of the ant's brain would establish its position at the head of its phylum. Its brain is not only large in proportion to its body, but has a kind of corrugation which reminds us of the convolutions of our own brains and those of the other higher mammalia. We know that ants sow seeds, clear the ground, gather and cure their grain, make slaves, and do many other things that indicate very high intelligence. We are not surprised, then, at what Mr. Hill writes of this apicide of Florida. He states that in the early evening, scouts are sent out in advance of the main army, which select the colony of bees to be destroyed and plundered. These advance agents may be seen running over the hive at the very dawn of the night. In such case, the colony of bees is usually doomed unless removed beyond the reach of the menacing host. Mr. Hill has frequently removed the imperiled colony with the result that an adjacent colony was attacked and destroyed.

This method has been the most successful of any tried. Mr. Hill reports that the bees show the utmost consternation when attacked by these ants. The chitinous crust, which in all ants is very hard, is specially so in the case of this bee-destroyer of Florida. The ant has immense strength, is very agile and alert, and, by use of its sharp, scissors-like jaws, is sure of victory. The hum of distress, and even of despair, made by the bees is so characteristic, that it would be quickly recognized even by the inexperienced.

As before stated, these attacks are always made in the night. During the time of the contest, thousands of ants may be seen running over the ground and the hives near by. The ants grasp the bees and the two may be seen whirling, one over the other, until the bee is hurled from the hive maimed or dead. This hand-to-hand conflict, if we may so call it, goes on until all that remains of the bees is, to quote Mr. Hill, "a crawling, wreathing mass of dismembered bodies drabbed in perspiration and honey." The victory is sure to come to the ants but is not without its fearful sacrifices. Hundreds of the ants are disabled or killed in the battle. These are mixt with the perishing bees and reach high up from the bottom-board between the combs. After the terrible carnage, the remaining ants feast upon the honey which is left in the comb and in the honey-sacs of the dead bees.

The immense numbers of these destroying ants can be easily imagined, as Mr. Hill states that he has burned thousands of colonies during the past two years. They seem to be proof against the use of bi-sulphide of carbon. When this liquid is used, they pick up their eggs and move to new quarters. The free use of gasoline and the torch seems the only practicable way to destroy the destroyers. Mr. Hill has invented a very ingenious way to protect his queen-rearing colonies from these ant banditti. He places them on a stand, the legs of which are so turned that a little basin encircles each leg. This little basin is made impervious by coating it on the inner side with paraffine. By keeping this full of kerosine or carbolic acid, the ants are unable to pass up the legs and so can not reach the bees. Of course the liquid has to be replaced as it evaporates.

Like all ants, this "bull-dog of Florida" has a sort of scale or hump on its narrow thorax. There are two sizes of the ants, the ordinary small workers and the much larger soldiers. The heads are very large, the eyes round and small, and the jaws very strong and sharp. The entire body has numerous hairs. Except the eyes and the abdomen of the soldiers, and the tip of the same in the smaller workers, which are black, the entire ant is red. As Mr. Hill has not sent me any specimens of the queens, I do not know how they differ from the others except as very likely they are larger and will show stubs of wings. The queens of all ants, as also the males or drones, have wings and fly

forth to mate. After mating, the workers or soldiers bite off the wings of the queen so that she is ever after held as a sort of a prisoner in the ant household where she performs no other duty than to lay eggs.

I have been explicit in this narration as it is a remarkably interesting case. Ants for the most part do little harm. When we see them visiting trees we may be almost assured that there are either scale-insects or plant-lice on the same trees. These scale or plant-lice secrete honey-dew and it is this which attracts the ants. The ants, then, do no harm here except, perhaps, to protect the scale and plant-lice from birds which are slow to visit plants on which ants abound. We all know that ants sometimes bore into trees. This tunneling, however, is rare except in trees more or less decayed. In such cases, however, the tunnels are often very numerous and the carving done by the ants is interesting to study. In California, where the ants are near trees, they sometimes do damage by destroying foliage. I have not seen this but have it from what I consider good authority.

The most grievous offense that the ants commit in our country is that of entering our houses and making themselves a nuisance on the lawn about the house. Strings dipt in corrosive sublimate will keep them from the houses, while burning with gasoline or suffocating with bi-sulphide of carbon is the easiest way to rid the lawn of their presence.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Moving Bees in Winter.

I have an apiary of about 50 colonies. Would you advise me to move them now? VIRGINIA.

ANSWER—Without knowing more about the case it is hard to answer. If you yourself expect to move, it will probably be more convenient for you to move the bees also. If you remain where you are, and the pasture is very much better at some place two or more miles away, it may be advisable to move the bees. If you expect to move the bees, and desire only to know whether the present is a good time to move them, it may be said in reply that it will be better to wait till the bees begin to fly in the spring. Still, if it is much more convenient to move them now, they may be moved carefully without danger of much harm.

Getting Straight Brood-Combs Moving Bees.

1. As I am a beginner in the bee-business, I would like to know what is the best way of getting straight combs in the brood-frames? I have 20 colonies, and I wish to run for extracted honey another year. The past year I worked for comb honey, so the brood-frames are in such a shape that it will be difficult to extract a great many of them that I would like to get into.

2. And, furthermore, is it best to contract the space in the hive, when there is an extra frame in the hive that isn't filled?

2. After a swarm issues, can I move the old colony, say a half mile, without injuring them, to a different place, supposing that the swarm that issued would better be put back on the old stand? The reason that I ask is, I want to have them on the opposite side of the river. I have 20 colonies. CALIFORNIA.

ANSWERS.—1. The very best way to have combs built straight is to fill the frames with comb foundation. That makes a sure thing of it that the center of the comb will be in the center of the frame, and you may make sure at the same time of having all worker-combs.

2. It is not desirable to have any more space in the hive than can be filled by the bees, especially in winter, for it costs the bees extra to keep up the heat in that extra space.

3. Yes, it will be all right to move the mother colony

away a half a rod or half a mile. If you want to have the moved colony pretty strong, move it immediately after it swarms. But it is generally considered good practice to let the old hive stand close beside the swarm for a week and then move it. That makes the swarm very strong, but of course the mother colony is just so much weakened. The object desired is to prevent a second swarm, and also to make the first swarm strong for surplus. Moving the swarm a half mile will be much the same as moving it a short distance, only there will probably be not quite so many bees leave the old hive for the swarm, if the old hive is moved a long distance.

Storing Supers 10-Frame vs. 8-Frame Hive.

1. I am anxious to fix my surplus honey arrangement during the winter, but having been deprived of the use of the building I used for a shed, I have no place to store my supers where the temperature does not go much below freezing—in fact, I must leave some outdoors. Thru the kindness of the "gude wife," I can work in one end of the kitchen, but must store my traps elsewhere. Will freezing injure the foundation in the sections, provided they are kept dry and in the dark? By an eye of faith I see a shop and honey-house after next summer's big honey-crop!

2. Why is a 10-frame hive better for extracted honey than an 8-frame, as you advise New Jersey, on page 25? How about two 8-frame hives with queen-excluders between? HOOSIER.

ANSWERS.—1. Don't be worried about the freezing. It's probably a good deal colder here than where you live, and I've had thousands of sections filled with foundation stay in a place as cold as outdoors not only all winter but two or more winters, and I don't think they were hurt by it.

2. One reason for preferring the 10-frame hive is that it is safer for winter. There is more room in it for winter stores. There is not the same reason for restricting the brood-nest at any time for extracted honey that there is for comb honey. The bees will not do anything at comb honey in the supers so long as there is room below. But it is not quite the same with extracting-combs above. If they have old black combs above they will store it in them nearly if not quite as readily as below, and even if the extracting-combs are new they will prefer them to sections divided up into little compartments. Of course, you will need more than one story of 10 frames in the harvest, and you will be safer from having the harvest interrupted by swarming than if the queen were confined to 8 frames.

Mating of Queens—Growing Plants for Honey.

1. I have been reading "Langstroth on the Honey-Bee," and I find that it says that the queen mates with the drone while on the wing. I do not find that it states anywhere that queens mate in any other way. I have six clipt queens, and others that seem to be too large to fly, and I would like to know if they will be all right for breeding in the spring.

2. I wish to purchase some honey-plants in the spring, and would like to know what would suit this climate best. What kinds of clovers would you advise, and what kind of garden flowers? WEST VIRGINIA.

ANSWERS. 1. It is exceedingly doubtful whether queens mate any other way than on the wing. If the wings of a queen are clipt before she flies on her wedding-trip, or if by any means the wings of a virgin queen are bad so she can not fly, you may better kill her at once; she is utterly worthless, as all the eggs she lays will produce only drones. The six clipt queens are all right for the next spring, if they were all right in the fall, for a queen does not need to meet the drones each year, but only once for life.

2. Your best chance will probably be among the clovers. Alsike clover is one of the best, especially if the location is somewhat low and wet. Sweet clover will do almost anywhere, and will do well on poor land and on stiff clay. Very likely crimson clover may prove a success with you. It is very beautiful when in flower, and would be an ornament in the door-yard. Crimson clover is not usually sown in the spring, but it may be worth while for you to try some at that time, as in that case you will be a little ahead if it succeeds.

The Premiums offered this week are well worth working for. Look at them.

Convention Proceedings.

Report of the Proceedings of the 31st Annual Convention of the National Bee-Keepers' Association, held at Chicago, Ill., Aug. 28, 29 and 30, 1900.

BY DR. A. B. MASON, SEC.

(Continued from page 55).

DISCUSSION ON SHIPPING HONEY CONTINUED.

Mr. Aikin—I am glad Mr. Abbott has made his speech; I know now where Colorado, Arizona and Utah people can sell their honey.

Mr. Moore—I was going to ask him how he sold 30,000 pounds of honey a year?

Mr. Aikin—Don't bother yourself about that, Mr. Moore. In the first place, if we had barrels, we would have to let the Wisconsin people ship to Chicago, and from Chicago to Denver, and from Denver to Loveland; what would be the freight rate? Not less than first-class, or once and a half, or double first-class.

A Member—Couldn't you ship barrel-staves without all that freight?

Mr. Aikin—We would probably have to pay the freight on them just the same; whereas the tin comes to Denver and our cans are put up right in Denver, and distributed thruout the State and adjoining territory, and we have new tin cans. I don't know of anybody in our part of the country who puts up honey in second-hand cans. Last year we put our honey in five-gallon tin cans, otherwise called 60-pound cans. Those cans are made, it is true, out of light tin, and unless they are securely made, you can burst one of them almost as easily as you could roll off a log. When the honey is quite liquid, you put that honey into the cans and let it stand for four weeks, and then you can ship it across the continent and back again and it will be there just the same; it will be candy solid. At least all the honey I ever produced in Colorado, and that has been a good many car-loads, would be candy within a month, and will be as solid as any butter or lard you ever ship. But why put it in a 60-pound can? What trade are we catering to, anyhow? It has come out at different times here in this convention, and in other ways, that the great bulk of the honey we have been producing and taking such pains to get nice, good honey for people to eat, goes where? Into tobacco, into whisky or liquor of some kind or other—I don't know what all it is put into. A representative from one of the Chicago honey commission firms told us last year that the great bulk of the extracted honey they bought and sold did not go on the table as a table syrup. If that is true, use your old, dirty barrels if you wish to, but we in the West who have a good table "syrup" that can't be excelled anywhere in the United States, propose to put our honey into cans. It is the cheapest package we can get. Every old alcohol and glucose barrel is picked up by the farmers and others who want to take water on their ground for drinking purposes. The cheapest barrel we could buy would cost us \$100, it wouldn't hold anything except water, and not always that. It is true that we could take the barrels and put them out there and use them. I made a piece of furniture in Iowa out of walnut, and it was put up several years before it went to Colorado. It stood all right until I moved it to Colorado; after I got it in that dry climate, the cracks opened up until you could stick your finger thru. That is what the barrels would do if you ship them from a damp climate and let them stand a little time without redriving the hoops. I tried that once on some barrels I had in Iowa in use for three or four years. After they had stood in my shop, I filled them with honey, having the hoops driven tight and putting on iron hoops and drove them until I was afraid I would burst the hoops, and then ship them to Colorado and let them stand in the sun a few days, and then went around and could lift the hoops off from the barrels with a finger. If the honey had not been candied it would have been out on the ground. That cuts but little figure with Wisconsin and New York people, and you who have barrels and can use them and ship them to the factory. I am producing honey and working on a different line altogether. Mr. Moore wanted to know how I could sell 30,000

pounds of honey in my local trade. I am making it a staple, and as a staple it must compete with other sweets of equal grade—that means granulated sugar with some water poured into it to make a syrup. I am not catering to the fancy trade, but when the poor people of this country buy our extracted honey and use it as a syrup, they don't want to buy a barrel of it, and they don't want it to be expensive, either. They don't want to pay 25 cents, or even five cents, for a package that will hold five cents worth of honey. I am going to hit Mr. York real hard while I am on the floor, and if he undertakes to get after me, I want you to get between us. Some of you remember reading in the American Bee Journal an editorial by Mr. York criticizing those of us who want to put our name and address on our package, and he says, "Does the farmer put his name and address on the bags of wheat, and on his potatoes, and on his horses and cows?" taking the whole list of them, pretty much. "Does he put his name and address on them when he sends them to market?" The case isn't applicable at all; his argument is altogether lame. The wheat the farmer sells goes into a big bin with 1,000 other farmers' wheat; it is shipped in a car-load to the mill, the miller grinds it, and when it becomes flour, every sack of it goes out with the miller's brand on it, and it remains on it until it goes into the family to be consumed. When Mr. York buys my honey, if he buys it in barrels or 60-pound cans, and puts it up in little packages to sell to the retail trade, it doesn't make any difference whether I have my address on it or not, it becomes then Mr. York's honey; but when I ship my comb honey that goes thru his hands to the retail trade, and is never changed from the moment it leaves my hands until it reaches the retail store, my name has a right and my address has a right, to be on that package and remain there until it goes to the consumer, or until it gets into the store. I have a right to have my name and address on every separate section, and in proof of my position I will ask you if you can find any package whatever in foods that is sent out in any other way. The name and address of the packer or manufacturer is on that goods whenever the goods goes right thru to its destination in the original package; butter is so branded, eggs are not of course, because an egg is an egg, and it is out of the question from the nature of the product. Yet in the city of Denver, there is a firm, I have been told within the last few days, who are making a specialty of strictly fresh eggs, and when these eggs go out to the different houses around the city, they go out with the name and address of the firm putting them out and guaranteeing them strictly fresh and all right. Now, I will not take any further time on this particular phase of it. But why continue with the large package? why waste any more time with that? Do as I have been doing—put your honey into the small retail package right the first thing; put packages up in dozens, or any other way, just as all kinds of fruit and other things, and put them up and send them right to the consumer and let them be used as a table syrup. My honey is put in lard-pails 3, 5, and 10 pound sizes, holding 4, 7, and 14 pounds of honey. I put that honey into the pails at the honey-house. I refuse to sell it, except to people right by me, until it has been candied solid; then I take it to the stores, and the store salesmen in my town to-day don't want liquid honey, because they will pick it up and tip it on one side and read the honey-label and then set it down and go off. Every customer who wants to look at it will do the same thing. Directly the honey is oozing out around the rim. When it is candied, there is none of that trouble. I am sorry my honey isn't here. I made a shipment by freight but it has not yet arrived; otherwise I could show you all of this. I have the printed instructions right here, how to melt that honey, and the people can learn, and will learn, and when they come to the store they want a package that they can take home, some syrup to go on their table as a staple, and they don't want to pay any fancy prices for the package; it is simply to put on their tables. They want it in the cheapest package they can get, and so when it is in a candied condition they take it home and melt it, and everyone is better pleased. Some like it better in the candied condition, and want it put up in cans. I put it up so they can have it either way. If they want it they can take it in the pails and put them in their wagon and go home; it can be used in town or country, or in the muing camp; outing parties take it because there is no leakage, no bother getting to their camping-ground. Let us quit looking so much after the manufacturing trade and begin to put our honey onto the table of the family, and we will do two things—we will benefit the family, and we will take a lot of this honey away from the manufacturer, and they will be com-

ing after us to get our honey, and I think we will increase the demand. I have been selling honey very cheap—I won't tell you how cheap; I have been selling it very cheap, and some people said to me, "You are selling honey too cheap; you are killing the market." I said, Which would you rather I would do? You know if I send my honey to Denver I will have to compete with you? Do you want me to sell at home, or sell in Denver? I say the question comes to this point, if I have a crop of 30,000 pounds for sale, and enough to make the total crop right around a little village of 2,000 population—making the total crop 50,000, is that community going to consume 50,000 pounds of honey at 10 cents a pound when they can buy granulated sugar at 5½ or six cents a pound and make a splendid table syrup? No, sir, they will not. Mr. Abbott is catering to fancy table trade; Mr. Moore is doing the same thing. Let them put up glass packages, if they want to, for people who are willing to buy fancy goods; let a panic come, and there comes a time when you can't sell to that trade; but the family buys every day in the year; they want it all the time, whether times are good or bad. The family trade is best to depend upon. I said to our Denver people, if I put my honey on the market at 8, 9 and 10 cents a pound, as you want me to, the result will be the people are going to buy the sugar and leave the honey with me; then I have got to ship it. What will I do? Send it down to George W. York, of Chicago? If I ship in less than car-lots it costs me 97 cents a hundred pounds to get it here, and I pay freight on the package—barrels or whatever it is. Mr. York would probably want to pay six cents there for it, or seven in Chicago; my package costs me ½ of a cent; how much money have I left for that honey? If I ship to the general market it will net me, less freights, commissions and package, about 3 to 4 cents; and I said to the Denver bee-keeper, would you rather I would ship my honey and get 4 cents a pound, or sell it at home for 6 cents a pound and keep it at home? I am tending to my own business, I am not bothering you; when you can get more right at home than you can sell, don't put it on the market to compete with other people who haven't the local market, or can't get it. (Applause.)

Continued next week.)

Report of the California Association.

BY O. L. ABBOTT.

The members of the California Bee-Keepers' Association met at Selma, Fresno Co., Jan. 7th, and elected a board of directors, consisting of the following members: Dr. J. P. Johnson, J. W. Paine, J. S. Crowder, B. D. Vanderburgh, and C. M. Davis.

The following were elected as officers for the ensuing year: President, Dr. J. P. Johnson; 1st vice-president, J. S. Crowder; 2d vice-president, C. M. Davis; secretary, Prof. C. S. Taylor, Jr.; corresponding secretary, O. L. Abbott, of Selma; and treasurer, J. W. Paine.

Pres. Johnson read the annual report, showing among other things that the directors had purchased a car-load of cans and a car-load of cases at a saving to its members; that the Association had received and sold 118,732 pounds of extracted honey at 6 cents a pound; and that it had manufactured the wax into foundation for its members at a low cost per pound. The members showed their appreciation by a vote of thanks, and by re-electing the old board. Mr. Grimes was unable to serve as director another year, so Mr. Davis was elected to fill his place.

A committee consisting of J. H. P. Stephens, Prof. C. S. Taylor, Jr., and O. L. Abbott, was appointed to revise the constitution and by-laws, and report at the next meeting.

The meeting adjourned to the first Monday in February.
O. L. ABBOTT, Cor. Sec.
Fresno Co., Calif., Jan. 8.

The Chicago Convention Picture is a fine one. It is nearly 8x10 inches in size, mounted on heavy cardboard 10x12 inches. It is, we believe, the largest group of bee-keepers ever taken in one picture. It is sent, postpaid, for 75 cents; or we can send the American Bee Journal one year and the picture—both for \$1.60. It would be a nice picture to frame. We have not counted them, but think there are nearly 200 bee-keepers shown.

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

"DRONES" AT THE WORLD'S CONVENTION.

The world's bee-convention, as reported by Mr. Dadant, page 8, was quite an affair, even if it didn't amount to many bushels of beans to be stored in the elevator where we keep all our knowledge. It is something, however, to be informed that colonies with many drones store 5½ percent less honey than colonies with few. (This was only one trial involving but 10 hives.) For you know that things imported from far are worth more than home-made articles. Interesting to see that *some* foreign opinion thinks 5½ percent not enough advantage to proscribe the drones on. Let me state the drone's strongest case, as it looks to me: When a young queen flies, if she comes within sight of 10 drones there is a sort of selection—the one that gets ready first is the mate—and that one is presumably the *best* one in the lot, the one that will transmit the most vigor. Now if she comes in sight of a hundred drones, there is still selection, chance good for the best one out of the hundred being the parent. And to be sure of the queen's being seen by a hundred drones whenever and wherever she may fly, there needs to be lots of them. (Incidentally, I may remark that this consideration makes me very apathetic about the search for some way to control mating. We can not equal nature's selection if we had control, because we can not see which drone is the best.)

There is another thing not always thought of. If drones are few there is little or no drone-comb in the brood-chamber. This is not necessarily so, but practically it will generally be the case. With no drone-comb below we must expect more of it built in the sections. (Wish I knew more positively about this.) But why care how much drone-comb there is in the sections? I am not *sure* on this point, either, but presumably the drone size requires so much longer an arch of capping that it does not lend itself so well to that beautiful and beyond-all-praise style of finish in capping which is one of the important things that we want to work towards. When bees do the best their art admits of, even dark-colored honey looks temptingly white—almost too dainty to touch with a handkerchief—the honey itself not being seen at any point.

COMBS OF HONEY FOR WINTERING.

Mr. Aikin, usually reliable, seems to me to be getting, for once at least, into the doubtful regions where he says, page 821, that four solid combs of honey are better to winter bees on than the same honey in eight combs. I believe I would choose the latter of the two—with a preference for six combs, with a generous space on four of them in which the cells were either empty or only half full. It certainly looks as the bees were not quite satisfied with their position on sealed honey. And such a solid slab of comb, with one edge of it nearly down to 32 degrees—we can hardly see how it can help being a needless extractor of animal heat.

NO U. S. HONEY AT THE PARIS EXPOSITION.

Not a pound of United States honey at the French Exposition! Doubtless the gazing public did not cry for the lack of it—still, neither the fact itself nor that consideration puts us in a swing-your-hat frame of mind. Suitable thing to put in our smokers and smoke it. Page 822, (1900).

CONDITION WHEN COLONIES BUILD UP RAPIDLY.

"Workers with full sacs most of the time." Yes, sir; that's it, Mr. Aikin. That is the exact and definite condition under which a colony of bees builds up rapidly. A little money (or honey) in *general circulation* better than much carried by a few individuals, or lying in bank. It's all well to say "honey coming in," it's all well to say "plenty of stores on hand," it's all well to say "feed;" but if either of these exists where half the workers are on moderate rations, and not handling honey themselves, things will continue to go slow. At odd jobs, from time to time, let us have the terms of our talk brought to terms of precision, instead of so much allowing of them to "lie around loose." Page 7.

Bees in Fine Condition.

I have about 50 colonies of bees all put away in the cellar in fine condition, and expect they will come out all right in the spring.

E. C. SMITH.
Ashland Co., Wis., Jan. 14.

Finding a Queen.

I see by page 41 that our good friend, Mr. E. E. Hasty, evidently misunderstood my statement on page 792 (1900). What I wanted to say was that I always found the queen on the combs on that side of the hive *not* occupied by the ventilating bees at the entrance. Thus while the queen is pursuing her accustomed duties she enjoys the benefit and the comfort of a well-ventilated room without being exposed to the direct draft of cool air which is forced into the hive by the fanning bees.

I am fully satisfied that this means of finding the queen has real merit when rightly understood.

W. W. MCNEAL.

Scioto Co., Ohio, Jan. 18.

Poorest Season in 23 Years.

My 250 colonies are all packed on the summer stands, as usual, and seem to be wintering nicely. The past season was the poorest that I have had since I have been keeping bees (23 years), as I secured only one barrel of surplus honey.

The prospects are good for the coming season, and if promises are realized I am making preparations to increase from 100 to 150 colonies.

I have never undertaken anything that has paid me better than bee-keeping, for the money and time invested.

EMIL J. BAXTER.

Hancock Co., Ill., Jan. 11.

Bees Did Well—Honey for Smallpox.

My bees did first-rate the past season, considering the care they had, as I was away for three months during the best of the honey-flow. My children took care of them, and took off 120 pounds per colony, and left enough in the hives for winter stores. The winter has been dry, not very stormy thus far, and it has not been very cold; the bees have been out nearly every day, and the prospect is good for the coming season.

A honey-cure recipe for smallpox was published on page 40 (1897). I saw an account of it in another journal later in the year, but did not get the one that had the cure in. If you would please be kind enough to reprint it it would be doing the people in this part of the country a great deal of good.

The Bee Journal comes to me every Sunday morning, and it is a very welcome visitor.

JOSEPH A. LEWIS.

Navajo Co., Ariz., Jan. 17.

Maule's (35 new things for 1961) Seed Catalogue

You should, by all means, have this **most modern catalogue of modern times**. It is brimful and overflowing with good things in vegetable, farm and flower seeds, flowering plants, fruits, bulbs, etc. It contains **35 novelties in vegetables and flowers never offered before**, has 12 large pages, seven handsome colored plates and hundreds of illustrations. It gives practical, up-to-date cultural directions and offers many cash prices. The first edition alone costs over \$50,000, so while we send it free to all customers, we must ask others to send 10 cents for it, which amount they may deduct from their first order. You will make a mistake if you do not write to-day for this the Novelties Seed Book of the year. Address, **WM. HENRY MAULE, Philadelphia.**

3D4t Please mention the Bee Journal

worst variety will disappear, and the fever is immediately diminished. The matter attracts much attention. The remedy was accidentally discovered by a young girl who was down with the disease, who secretly refreshed herself with honey and water with the astonishingly curative results, and it was then tried on soldiers sick with the disease.

Bees Seem to be Wintering Well.

There has not been much winter here as yet, but it has turned colder to-night, with prospects of a big snow-storm or ice spell. Bees are wintering well, seemingly.

J. WILEY MOUNTJOY.

Anderson Co., Ky., Jan. 17.

Wintering Bees in a Cyclone-Cellar.

I have 49 colonies in winter quarters—30 in my cyclone-cellar, and 19 in a neighbor's. I put them away about the first of December, and they appear to be doing well. I find the cyclone-cellar the best place to winter bees, as I have lost only two colonies in six years, and they were weak when put away. Last winter I put 10 colonies into the house-cellar, and lost three of them after taking them from the cellar, and the others were weak and didn't do much all summer.

The bees stored very little spring honey, but the fall flow was good. I got 1,500 pounds in all, over 900 pounds being comb honey. My best colony stored 169 sections, and the next best 105 sections. No. 1 was an old colony, and did not swarm during the summer. No. 2 was a swarm which came off June 18th; but I had 11 colonies that did not give me a pound of honey.

I use the 8-frame and the 10-frame

Wintering Well—Prospects Good.

Bees are wintering in perfect condition, and prospects for a good season this year are very fair. **C. H. DIBBERN**, Rock Island Co., Ill., Jan. 22.

1900 a Poor Season.

I started in the spring of 1900 with 62 colonies, and secured about 500 pounds of comb honey, and no increase. It was the poorest season we have had in this locality in 10 years. I put 58 colonies into winter quarters, 9 of them being light.

THEO. REHORST, Fond du Lac Co., Wis., Jan. 15.

Report For 1900—Sweet Clover.

The season of 1900 was the poorest in this locality since I have been keeping bees (8 years), with the exception of the "dry" year of 1894. There was a light honey-flow from sweet clover and basswood, but it came very slowly. I secured about 1200 pounds mostly comb honey, from 60 colonies, spring count, and increase to 73. I was pretty busy in the fall building a new house and getting moved, so I didn't give the bees as much attention as usual, and

some colonies are pretty light, as we had no fall honey-flow.

One man two miles from me had two colonies last spring, increased to 8 by the let-alone plan, got no honey at all, and now has one colony! That is, he did have one left about a month ago, when I last saw him.

We had considerable rain here last fall, and clover looked fine. The great drawback to clover here, tho, is the dry, cold winter, without snow to protect it. The ground is full of moisture this winter, and we are hoping it (the clover) will come thru in good "shape." Sweet clover always comes thru all right—I don't believe a Klondike winter would kill it, for it's almost a "sure thing." It does not stay in bloom so long here as we read of it doing in some other localities. It begins to bloom about July 1st, or a little before, and is all gone to seed and almost all dead before August 1st. Is it because of "locality," or have we a peculiar strain? It is the "short-tubed" clover, and if one has enough of it, it will not be necessary to breed "longer-tubed" bees.

I wish the "Old Reliable" and its numerous family a happy and prosperous season. E. S. MILES.

Crawford Co., Iowa, Jan. 12.

Reliable Incubator and Brooder Co.—The following letter from the Inspector General of the Paris Exposition has been received by the Reliable Incubator and Brooder Co., Quincy, Ill., and its flattering statements, since they are fully deserved, will be enjoyed by the many friends and users of Reliable machines all over the land. We are very glad to give it publicity:

Paris, Nov. 9, 1900.
THE RELIABLE INCUBATOR AND BROODER CO., Quincy, Ill., U.S.A.

Gentlemen:—I have the honor to remit your certificate of admission to the Paris Exposition of 1900, and take this opportunity to compliment you upon your successful attainments at the Paris Exposition.

Your unique, interesting and instructive exhibit in its handsome pavilion has entertained hundreds of thousands of visitors, whose unanimous opinion and active interest manifestly desire you to be the best exhibitor of the poultry industry in the United States.

Signed, HON. C. DE RUFE D'ARNOX, Inspector General.
Issued under the authorization of
The Hon. Delawey Belleville,
Director General.

Juvenile Poultry Raisers.—As time goes on it becomes more necessary to give our boys and girls practical education. Agricultural colleges are springing up in every State. We are sending our next generation of farmers to these schools now to fit them for battling with close competition on all matters that pertain to successful farming.

The schools of training are commendable, but the large percent of the farmers in the future will come from the farms without the advantage of science as developed at these schools. It therefore stands us in hand to make the best use of our home schools—the farms. Every boy and girl likes to own something, and, for the educational purposes alone, they should own something. Nothing fills the bill better than an incubator and a flock of poultry. It cultivates a sense of care and business management that would be lacking when they were called on to do business in a competing grocery store. In their time of life that impressions are permanent, good or bad. The writer of this was a boy once, raised on a farm; owned every colt—or rather owned a new colt each spring—owned it until it became real valuable, then he had the privilege of trading it for the youngest again and was educated to think the young colt more valuable for a boy than a colt old enough to bring a good price. The result of this line of training and encouragement, he landed in business at 21 a regular pumpkin-head to do business. The farm had an attraction for him, he could see nothing in it but plow and harrow and doing without money from crop to crop. I am not blaming Dad, he simply did not know how to educate a boy. Had there been an agri-

cultural college or other school that occurred to him to be a good thing for a boy, money would not have stood in the way. As a boy stated, he was not aware that he run the best school on earth, right at home among relatives.

Of course, we would rather the farmer would buy his boy an incubator, but rather than see the boys grow up without ideas of business care and management, it would certainly pay really to give them a start, even if it was nothing more valuable than the hen and chick. Boys and girls like to own something; as soon as they are old enough to play marbles or jump the rope, they will want to own the marbles and rope at least. N. M. JOHNSON.

Inventor of the Sure Hatch Incubator.

A Model Incubator Factory.—The new factory erected last summer at Rose Hill by the Marilla Incubator Company, is thoroly equipped in all its departments with modern, up-to-date machinery for the manufacture of incubators and brooders. In many respects it is one of the most complete incubator factories in the country. Since its completion it has been filled with busy workmen building this famous set of incubators and brooders. All possible care is taken in the factory to see that everything about the machines is exactly right; the material is carefully inspected before it passes into the factory; only skilled mechanics are employed, and every finish machine is tested before being crated. It is this extraordinary care which enables these manufacturers to sell their machines on the 30-day free trial plan, and they tell us that not one machine in a hundred ever comes back. The new catalog of the Marilla is a handsome book full of practical information about incubation and brooding, and explaining in detail the Marilla hot-air tank or radiator and mercury regulator—special features of this incubator—in which we know of no other machine will be interested. Send for it, being sure to mention the American Bee Journal when writing.

Queen-Clipping Device Free...

The MONETTE Queen-Clipping Device is a fine thing for use in catching and clipping Queens' wings. We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. Address,

GEORGE W. YORK & COMPANY,
118 Michigan St., Chicago, Ill.

Good Instruments.

Don't confuse these instruments with cheap "jargon" counter offers. They are high grade, fully guaranteed, instruments for MICHIGANS.

VIOLIN—Amati model, choice of 3 full body trimmed, Brazil wood bow, pearl sliding on, 110¢. **FLUTE**—Amati model, extra set of strings, rose, with 8¢. My Price \$6.27.

MANDOLIN—Hofner standard case, nearly mild, Spanish cedar neck, celluloid trim, ebony finger board, best quality patent bridge. Full leather bound canvas case. My Price \$8.50. **MANDOLIN**—Solid Rosewood body, celluloid trim; veneered head, piece, beautiful finish. Elegant French Polish. Patent head, engraved all-piece. Worth \$10.00. My Price \$7.25. Full leather bound case, extra set of strings and tortoise pick. Send for circulars of high grade musical instruments.

Charles A. Hoke, the Auditorium, CHICAGO.

The Emerson Binder.

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have the "Emerson" no further binding is necessary.

GEORGE W. YORK & CO.,

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Jan. 19.—Honey is selling slowly; this applies to all grades with the exception of white clover and basswood comb honey, which sells readily at low providing it grades No. 1 or better. All other kinds of white comb honey sell at from 14¢ to 15¢, and candied white comb at from 20¢ to 21¢; travel-stained and off-grades of comb, 13¢ to 14¢; amber, 12¢ to 13¢; amber extracted, 7¢ to 7½¢; dark and buckwheat comb honey, 9¢ to 10¢. Extracted, white, 6¢, 7¢ to 8¢; basswood and white clover bringing the outside prices; buckwheat and other dark grades, 6¢ to 7¢. Beeswax, 25¢. R. A. BURNETT & Co.

KANSAS CITY, Jan. 22. Fancy white comb, 15¢ to 17¢; amber, 13¢ to 14¢; dark, 9¢ to 11¢; demand good. Extracted, 7¢ to 8¢; demand quiet. Beeswax, 26¢ to 27¢.

W. R. CROMWELL PRODUCE CO.,
Successors to C. C. Clemens & Co.

BUFFALO, Jan. 17.—All kinds of honey are so quiet it is difficult to make a sale. Occasionally some sells, fancy 14¢ to 15¢; few, 10¢; choice and No. 1, 12¢ to 14¢; few, 14¢; but dark, 9¢ to 10¢, and all kinds in liberal supply; some may have to be reconditioned. Beeswax, 25¢ to 27¢, and wanted in Buffalo. Beeswax, 22¢ to 27¢.

BATTERSON & Co.

ALBANY, N. Y., Jan. 18.—Honey market is dull on all grades now, with light stock and light demand. White comb in good condition, not candied, 15¢ to 16¢; mixt, 13¢ to 14¢; buckwheat, 12¢ to 13¢; mixt, 11¢ to 12¢; extracted, white, 8¢ to 9¢; mixt, 6¢ to 7¢; dark, 5¢ to 6¢.

H. R. WRIGHT.

BOSTON, Jan. 18.—Fancy No. 1 white in cartons, 17¢; A No. 1, 16¢; No. 1, 15¢ to 16¢, with a fairly good demand. Absolutely no call for dark honey this year. Extracted, white, 8¢ to 9¢; light amber, 7¢ to 8¢; Beeswax, 27¢.

BLAKE, SCOTT & LEE.

CINCINNATI, Jan. 16.—Market very quiet. No change in prices. Fancy white comb sells for 16¢. Extracted, dark, sells for 5¢ to 6¢, and better grades bring 6¢ to 7¢. Fancy white table honey brings from 7¢ to 8¢. C. H. W. WEBER.

NEW YORK, Dec. 22.—Fancy white, 15¢ to 16¢; No. 1 white, 14¢; No. 2 white 12¢ to 13¢; amber, 12¢ to 13¢; mixt, 11¢ to 12¢. Demand in fairly good demand at 7¢ to 8¢ for white, and 6¢ to 7¢ for amber; off grades and Southern in barrels at from 6¢ to 7¢ per gallon, according to quality. Not much demand for extracted buckwheat as yet. Some selling at 6¢ to 7¢. Beeswax firm at 28¢.

Demand continues good for comb honey; supply fairly good. Extracted white and demand with enough supply to meet requirements.

HILDRETH & SEGELKEN.

DETROIT, Jan. 19.—Fancy white comb, 15¢ to 16¢; No. 1, 13¢ to 14¢; dark and amber, 12¢ to 13¢. Extracted, white, 7¢ to 7½¢; amber and dark, 6¢ to 6½¢. Beeswax, 26¢ to 27¢. M. H. HUNT & SON.

SAN FRANCISCO, Jan. 9.—White comb 13¢ to 14¢; amber, 11¢ to 12¢; dark, 8¢ to 9¢. Extracted, white, 7¢ to 8¢; light amber 6¢ to 7¢; dark, 5¢ to 6¢. Beeswax, 26¢ to 27¢. Stocks of all descriptions are light, and values are being as a rule well maintained at the quoted range. Firmness is naturally most pronounced on light amber and water white honey, the latter being in very scanty supply.

HONEY MARKET.—We may have a customer within a short distance of you who wants your honey or beeswax. We are in close touch with all the markets; therefore write us regarding your crop, stating quantity, quality, and lowest cash price. References—Either Bank here for any business man in this city.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it, but if the “Novelty” is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the “Novelties,” your POCKET KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this beautiful knife, as the “Novelty” must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00). We will club the Novelty Knife and the Bee Journal for one year, both for \$1.00.

GEORGE W. YORK & CO., 118 Mich. St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

AMERICAN BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., FEBRUARY 7, 1901.

FORTY-FIRST YEAR
No. 6.

WEEKLY

February.

The low-slanting Sun, which for many a day
Has played childish bo-peep with work,
Is slowly but surely retracing his way,
Which means he will no longer shirk.

In prodigal mood he deserted the North—
With harvests a plenty in store—
To riot with beauties of tropical birth,
And sensuous gardens explore.

Repenting, he turns toward the land where the bloom
Is waiting his slow, silent tread.
Thrice welcome the wanderer back, and make room
For music and joy we thought dead!

The bees and the birds have been silent and glum
Since cheery Old Sol traveled South;
The flowers lie asleep till this rover shall come
And kiss them right square in the mouth.

BY EUGENE SECOR.

PUBLISHED WEEKLY BY

GEORGE W. YORK & CO.

144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50c a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec'00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

Reformed Spelling.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philologist Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th 1899 Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we elope it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street,

CHICAGO, ILL.

THE BEST WHITE**ALFALFA
OR
BASSWOOD****Extracted Honey****ALL IN 60-POUND TIN CANS.****ALFALFA
HONEY.....**

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

**BASSWOOD
HONEY.....**

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

We have a good stock of the fine WHITE ALFALFA and WHITE BASSWOOD EXTRACTED HONEY that we can ship by return freight. Most bee-keepers must have sold all their last year's crop long before now, and will be ready to get more with which to supply their customers. All who have had any acquaintance with the above-named honeys know how good they are. Why not order at once, and keep your trade supplied?

Prices of Either Alfalfa or Basswood Honey:

For the purpose of selling again.

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are boxt. This is all

Absolutely Pure Bees' Honey,

The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:

I've just sampled the honey you sent, and it's prime. Thank you. I feel that I'm something of a heretic, to sell several thousand pounds of honey of my own production and then buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drink, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honeys of more market flavor, according to my taste. C. C. MILLER.

McHenry Co., Ill.

Order the Above Honey and then Sell it.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

26 cents Cash paid for Beeswax.

upon its receipt, or 28 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO.

This is a good time to send in your Beeswax. We are paying 26 cents a pound—CASH—for best yellow.

AMERICAN BEE JOURNAL

* Editorial. *

National Bee-Keepers' Association.

—General Manager Secor has sent us the following copy of the report of the committee appointed by the Board of Directors of the National Bee-Keepers' Association to count the ballots cast at the annual election held in December, 1900:

CHICAGO, ILL., Jan. 23, 1901.

HON. EUGENE SECOR,

General Manager National Bee-Keepers' Association, Forest City, Iowa.

DEAR SIR:—The undersigned committee selected to count the votes cast by the members of the National Bee-Keepers' Association in December, having performed their duties, find the following result:

Total number of votes cast 235

FOR GENERAL MANAGER—Eugene Secor, 234; George W. York, 16; Dr. C. C. Miller, 3; Wm. A. Seiser, 2; balance scattering, 1 each.

FOR THREE DIRECTORS—W. Z. Hutchinson, 237; A. J. Root, 233; E. Whitecomb, 213; George W. York, 25; G. M. Doolittle, 17; Dr. C. C. Miller, 12; Herman F. Moore, 13; E. T. Abbott, 11; C. P. Dadant, 10; N. E. France, 8; O. O. Poppleton, 6; Frank Benton, 5; C. A. Hatch, 4; W. L. Coggeshall, 3; Thomas G. Newman, 2; H. G. Acklin, 2; P. H. Elwood, 2; Prof. A. J. Cook, 2; Eugene Secor, 2; balance scattering, 1 each.

Respectfully submitted,

GEORGE W. YORK, *Comm.*

HERMAN F. MOORE.

The officary of the National Association now are as follows:

President—E. R. Root.

Vice-President—R. C. Aikin.

Secretary—Dr. A. B. Mason, Toledo, Ohio.
General Manager and Treasurer—Eugene Secor, Forest City, Iowa.

Board of Directors—E. Whitecomb, W. Z. Hutchinson, A. J. Root, E. T. Abbott, P. H. Elwood, E. R. Root, Thomas G. Newman, G. M. Doolittle, W. F. Marks, J. M. Hanbaugh, C. P. Dadant, and Dr. C. C. Miller.

Single vs. Double-Tier Cases.—Some time ago Gleanings in Bee-Culture published an editorial on the subject of comb-honey shipping-cases, saying that years ago the first were double-tier, holding 48 pounds, but some thought them too heavy. After some time similar cases were made holding just half the amount, and finally 12-pound single-tier cases. The latter were so convenient that naturally the 24-pound single-tier appeared. Bee-keepers and commission men, after using the latter, decided that it was just the thing. The objection to the double-tier cases was that should any of the combs in the upper tier of sections become broken they would leak down over the lower tier, and thus daub them also. During the past few years there has been

scarcely a double-tier case used in the East and central West, but in Colorado the bee-keepers seem to hold to the double-tier cases with two glasses separated by a strip of wood.

Editor Root says that during all the time the many were advocating single-tier cases Dr. Miller still clung to the 24-pound two-story case. The Root Company, like many others who handle large quantities of comb-honey, advocated the single-tier cases either 12 or 24 pound, but it seems that after getting and disposing of some car-loads of honey from Colorado the past few months, put up in double-tier 24-pound cases, their prejudice against them began to wane; and now Mr. Boyden, their honey-man, and also the freight-handlers, prefer the 24-pound double-tier cases. Mr. Root thinks that while it may not be possible to give fully the reason, it may be on account of the double-tier case being cubical in form, and thus more easily lifted and handled than when spread out in a single tier. He says, "Handle a car-load of it and be convinced." He thinks the double-tier case is more symmetrical in appearance, conforming more with other packages holding staple goods.

Mr. Root also says that the double-tier case is now used "with drip paper under the upper set of sections as well as under the lower one, so that the one objection to honey leaking from the upper to the lower set has been removed."

Galvanized Iron vs. Tin. A stray Straw in Gleanings in Bee-Culture says:

"Australians seem agreed that galvanized iron does well to hold honey so long as honey without air touches the surface; but let the surface be simply daubed with honey so the air can get at it, and chemical action at once takes place.—A short time ago the Australians seemed to be agreed that galvanized iron was not fit for either extractors or cans, for holding honey. The verdict in this country seems to be that for extractors it is safe, because the honey is supposed to remain in the machine only long enough to run out. But I believe myself that storage-cans of less than one or two barrel capacity should be made of tin. If larger, galvanized iron will be all right. EDITOR."

Queens by Mail.—In the American Bee-keeper Editor Hill refers to the discussion at the Chicago convention in regard to the effect on queens sent by mail. It will be remembered that there were those present who thought that queens were quite a good deal injured in going thru the mails, and also others who did not think they were materially affected. Referring further to the matter, Mr. Hill says this:

To take a queen from active egg-laying and confine her in a mailing-case for several days is such a very abrupt change, resulting in a

suspension of her natural function, that even a casual thought of it impresses one with the probability of its detrimental effect; and, indeed, it may be that very prolific queens are sometimes injured in this way. We believe, however, that it will rarely be found that the injury is permanent. Some of the best queens that we have ever owned have come to us thru the mails, during the honey season. Some very inferior ones have likewise been received. We might be prone to charge this inferiority to the above cause, but the most inferior lot of queens that we have ever bought were confined only about 20 hours; and then, upon three full frames of brood and bees. There were 50 of them in the lot, and but five or six of them proved to be worth keeping, altho they were of the high-priced kind.

The National Bee-Keepers' Association.—We received the following letter recently:

EDITOR AMERICAN BEE JOURNAL:—I have just learned thru the Rural New Yorker the result of the Uter vs. Uter suit against the bees. Hurrah for the National Bee-Keepers' Association! Had it not been for that suit would never have been appealed, and then bee-keepers the whole world over would have had to take a back seat, and would have been hounded around by anybody and everybody who chose to do so. I wonder if bee-keepers thruout the country realize the benefit they have already, and will hereafter receive from the actions of the Association. Too many good things can not be said in praise of it. It seems to me the Association is the mainspring to bee-keepers; that is, it is the foundation upon which we as bee-keepers can build our hopes of having our rights protected.

I am glad my ideas have been stirred up sufficiently to cause me to become a member of the best association we ever had. Enclosed find \$1.00 which you will please forward to General Manager Secor. A. H. SNYDER.

Uster Co., N. Y., Dec. 31.

We are glad Mr. Snyder wrote us as he did. His letter ought to stir up others to follow his good example.

Really, we don't see how any one that is at all interested in bee-keeping, and in seeing their rights upheld, can fail to appreciate the great value of the National Bee-Keepers' Association. There ought to be a grand stampede on the part of those still outside the Association. They should join by the hundreds, and do so at once.

We are ready at all times to receive the annual dues (\$1.00) from any and all, and then forward the money to General Manager Secor, who will promptly mail a receipt to each.

Past-board-Candy Queen-Cages.

During the past season a number of queen-breeders used mailing cages which had a piece of perforated cardboard at the candy end of the cage, instead of the usual cork that has been used for years. The idea was that the bees would tear away the past-board, then eat thru the candy, and thus liberate the queen. It seems that some bee-keepers who received

queens in these cages were not successful in introducing, and attributed the failure to the pasteboard. In a *Straw Straw in Gleanings in Bee-Culture* Dr. Miller had this to say about it, he having used a number of the pasteboard cages:

The American Bee-keeper, speaking of the pasteboard cage made of introduction, says: "At this writing numerous reports are coming in which show that failure more often results thru the use of the new plan than with the older method." Isn't your verdict a bit hasty, Mr. Hill? In the few hundred cases that have come within our knowledge, there have been rare exceptions when the bees did not remove the pasteboard, but that is the only objection. As to the rest, there is undoubtedly additional security from the longer time it takes to remove the pasteboard; and, without being sure of it, my present notion is that fewer failures will occur with the pasteboard.

Editor Root had this comment on the above paragraph:

A good deal depends upon the kind of pasteboard and the manner it is put in over the candy. The first cages we sent out had the strips cut too wide. We now cut them much narrower, so that the candy is exposed on both sides to the bees, as well as thru the perforations in the center. It is true, there have been failures by this plan of introduction; but the failures have been due, I think, in all cases, to too much pasteboard or to the wrong kind of pasteboard.

Should Brood-Combs be Renewed? is a question sometimes asked, and answers to the question vary according to the place. It seems just a little strange that views on opposite sides of the ocean should be so far apart. Good authorities on the other side say that when brood-combs become old the cocoons left in the cells from year to year diminish the space for the growing larva to such an extent that it is not advisable to allow combs to remain without renewal, the proper time for renewal being given by different authorities at four to ten years. On the other hand, beekeepers in this country pay little or no attention to the matter of renewing combs, counting that age alone does not rule them out. Some of them say they have combs 10, 20, or more years old, and can see no difference in the size of the bees reared in them. But a slight difference in size might not be easily discerned with the naked eye, and those who advocate renewal of combs argue that as each bee that emerges from a cell leaves a deposit in the way of a cocoon, the diameter of a cell must become less, and as a result the bees reared therein must be less.

The only way to settle the matter definitely would be to have instruments sufficiently delicate to measure a very small fraction of an inch, to find by actual measurement the difference in diameter between cells of new and old comb. Such measurement has been made by Editor Root, and unless the specimen of comb measured by him was exceptional, we may thank him for having set the question at rest, and congratulate ourselves that the bees do not show a lack of good judgment when they show their preference for old comb. Mr. Root had sent to him a specimen of worker-comb 25 years old, and says:

There are just as many cells to the square inch, of course, but the bottoms of the cells have from eight to ten layers of cocoons, while the sides of the cells have only one, and at most two layers. This would seem to indicate that, when the diameter of the cells gets too small, the bees remove the excess of

cocoon walls, but leave the bottoms until they get a packing of ten layers. This reduced depth can, of course, be corrected by adding more wax to the ends of the cells. Now let's see if this is true. Then, I've stop to measure, and find that the thickness of the comb is from one inch to one and one-sixteenth thick. Thickness of new brood-comb is about seven-eighths; and, if so, this 25-year-old comb has been thickened from two to three sixteenths because of the packing of nine and ten layers of cocoons in the bottom of the cells. The other fact seems to be that the diameter of the cells has not been reduced all the way. If this is true with other old combs, then worker-bees in a 25-year-old comb will be just as large as in one six months old. This I am inclined to believe correct, because Nature would surely make some provision for the excess of wall-linings.

Weekly Budget

Dr. J. P. H. BROWN, of Richmond Co., Ga., writing us Jan. 23d said:

"Bees did fairly well the past season, and where attention was given they will safely pass over till they can gather from natural sources in the spring."

Mr. H. D. CUTTING, of Lenawee Co., Mich., as a good many of our readers know, has been totally blind for several years. On Jan. 1st Mr. Cutting mailed us a picture of himself and his dog "Duke." This dog is one of Mr. C.'s most intimate friends. He is 2 feet 11 inches high, which is about 5 inches higher than an ordinary dining-room table. He weighs about 165 pounds. Mr. Cutting says, "He is very kind to me, also a great pet of our family."

Mr. Cutting is doubtless a great many will remember, had charge of the Michigan apian exhibit at the World's Fair here in Chi-

cago for us to see him, even if he can not see us.

MR. THOMAS G. NEWMAN, in his *Philosophical Journal* for Jan. 1901, had this to say about our New Year's troubles:

FIRE.—We regret to learn that the office of the *American Bee Journal*, of Chicago, Ill., as well as the bee-supply and honey departments, were wrecked by fire and water on Jan. 1st. This was a disastrous way of beginning the New Year. As the editor of the *Philosophical Journal* was editor of the *American Bee Journal* for nearly 20 years, he deeply regrets this disaster. The present proprietors (Geo. W. York & Co.) have our warmest sympathy and best wishes for surmounting the loss. As they issued the next week's *Bee Journal* on time, we feel that they are equal to the task.

MR. F. L. FIELD was one of our New York subscribers until we received the following letter, Jan. 23d:

Dear Sir

Now I want you to stop that paper of yours I have had to or three little papers sent me before that I could not stop it when paying up. Now I want this to end it. If you send it on you will never receive any pay when I subscribe for a paper I am capable of knowing how long I want it with any of your help. F. L. FIELD.

The above is as nearly like Mr. Field wrote it as we can show it in type. His subscription was in arrears only since July 1, 1900. If he had been kind enough to have sent us a postal card when it expired, asking us to discontinue sending it, we would have attended to it. But Mr. Field, very likely wanted the *Bee Journal*, else he would have notified us in a courteous way over six months ago.

Many subscribers express their thanks to us for continuing to forward the *Bee Journal* to them after their paid subscription expires, or until such time as it is more convenient for them to remit. We are always glad to do

Mr. H. D. Cutting and "Duke."

cago in 1893. At one time he was also president of the National Bee-keepers' Association, being for a number of years one of the leading beekeepers in Michigan. His many friends will sympathize with him in his sad affliction, for none of us who have the proper use of our eyes can realize what it means to be entirely deprived of it.

Mr. Cutting has earnestly solicited us to visit him some time—a thing which we would like very much to do, and are still hoping that we may have the pleasure of spending a day or two at his pleasant home. It will be a de-

this, even if occasionally we do receive such a cross-grained letter as Mr. Field wrote us.

We would never think of forcing the *American Bee Journal* on any one, and always stop sending it when asked to do so. We do feel, however, that when a man continues to take it from the post-office and reads it, he ought to be willing to pay for it.

Of course, whenever any one finds he does not want it any longer, then he should pay whatever is due, and courteously request its discontinuance. To do this is only common honesty and ordinary gentlemanliness.

Convention Proceedings.

Report of the Proceedings of the 31st Annual Convention of the National Bee-Keepers' Association, held at Chicago, Ill., Aug. 28, 29 and 30, 1900.

BY DR. A. B. MASON, SEC.

(Continued from page 75).

DISCUSSION ON SELLING HONEY CONTINUED.

Mr. Moore—Mr. Eaton, the chemist of the Pure-Food Commission, would like to say a word or two about labeling packages, from the standpoint of the Pure-Food Commission.

Prof. Eaton—There is one interesting thing just brought up I forgot to mention, and that is, about the name and address of the manufacturer being on every package; that is the only way honey can be sold in this State, at least in the package sold to the consumer, the name and address of the manufacturer must be on the package, not only in the case of honey but every sample of food. There is just one other thought that came to me as Mr. France, I believe, was speaking about putting honey in glucose-barrels. Of course, perhaps you are anxious to avoid the appearance of evil; I don't believe that is quite as necessary as it is to avoid the evil itself. It is the adulteration we are looking after. If they get the honey pure, they don't care so much for appearance. I have noticed the worst adulterated honey comes in the fanciest package.

Mr. York—There are several things I would like to say. I think some one said that the National Biscuit Co. used more honey in barrels than in cans, or preferred it in large packages. If I am not mistaken, they use more honey put up in 60-pound cans than in barrels. The "body-blow" that Mr. Aikin thought he gave me, I did not feel at all. In fact, I would hardly have known that he was aiming at me. He says he has a right to put his name on every package of his honey. True, he has a perfect right to do so, but if I bought his honey I would take it off mighty quick. Usually the way I put up my comb honey for sale is with these words on the printed carton: "York's Honey, Absolutely Pure, Always the Best." Suppose I sell that to grocers and they take it out of the carton and find R. C. Aikin's name and address on the section. Wouldn't the grocers think York was a fraud? I have been advertising; I have kept a man out at high expense to push "York's Honey," and I think I have a right to have my name on that honey and not the bee-keeper's name. It is none of the public's business who produced that honey. When I buy Mr. Aikin's honey, it is *my* honey, and I have a perfect right to do what I please with it. I can throw it in the Chicago river if I want to, or give it to anybody. It is not necessary for the consumer to know whose bees produced it. There is a great difference between the adulterated product and the honey produced by the bees. Mr. Eaton said the label must be on every package—not the label of the honey-producer, but of the man who puts it on the market.

Mr. Eaton—Either the manufacturer or the packer; some one that we can hold responsible.

Mr. York—So I say that every package that I put out in that shape I have my name on, and I will guarantee it. I am not working in Chicago alone. I boom the business of Mr. Aikin when I pay him his price for his honey. For instance, I know Mr. Moore sells honey in this city and gets a good price for it. If he buys Mr. Aikin's extracted honey, and puts Mr. Aikin's name on the pails in which he retails it in Chicago, the consumer would thus learn that it was R. C. Aikin who produced it, and think that next time he (the consumer) will get his honey direct from Mr. Aikin. Then Mr. Moore might as well go to hock-carrying. He can't afford to live here in the city and pay his expenses to advertise Mr. Aikin's business. Do you see the point? When I buy a bee-keeper's honey, that honey belongs to me, and I stand back of every pound of it that I offer for sale. I don't know that I can say anything more than I have. I have had at least some experience, and believe you all know how I stand on this question. If you had had the experience I had last winter with honey, I am sure you would not

use another honey-barrel while you keep bees. They are dangerous. I lost one finger-nail myself from handling honey in barrels! You will remember while Mr. Bishop was on the platform, yesterday he spoke of a bung coming out—

Dr. Mason—That was a can and the cover blew off! [Laughter].

Mr. York—I was going to tell about the 28 barrels of honey that I had standing on end in my warehouse; before I knew it, the honey was leaking all over the floor, and I had to transfer every barrel of that into tin cans.

Mr. Poppleton—The honey we had did the same thing in cans.

Mr. York I lost scarcely any honey at all in cans. But Mr. Burnett knows more about this subject than all of us put together. He has handled much honey in his 20 years in Chicago, and I would like to have him close this discussion, if he will.

Mr. Burnett—I thought perhaps you had enough yesterday, but this discussion brings to my mind a little incident. I will relate it. If Dr. Mason takes exception to it, you must draw your own conclusions. We will lay the scene on the bridal tour. After a little lapse of time in conversation, the lady turning said, "Who is sweet?" The reply was, "Both of us." Now, this discussion on packages has been sweet; it is all right, and the condition of the package will tell the tale when the honey is taken out. If the package was properly prepared for the honey, there will be no difficulty with the honey when it is taken out. I have been given considerable credit here that I am not entitled to, in my opinion, and therefore I would depend wholly upon the circumstances and the conditions in which you are situated. I know to put honey in a barrel in some places would be almost to waste the honey. I don't know that there is any place where honey in a can would be wasted, providing the can was all right; so the can may have that much advantage over a barrel; if they are leaky and rusty, why the barrel is perhaps preferable to cans as now used. One gentleman here spoke about using second-hand cans. I never came nearer getting into trouble than I did once on that question. I have been very, very careful when asked by bee-keepers what sort of package to use for their honey, for unless I knew all the circumstances connected with their situation I could not advise, and on many other questions I have endeavored to be conservative; but I knew where new cans were bought for honey, that nothing had been in those cans before; I bought the cans by the car-load and shipped them to parties who filled them with honey, and sold the honey, and as I could get the cans and cases back from the parties to whom I sold the honey at a low price compared with the cost of new, it seemed to me those cans ought to be all right, and as far as I could see they were all right; so I wrote to my correspondent about the matter, and he at once grasped the idea that that was just the thing, that they could save at least a half a cent a pound on their honey by so doing. Having committed myself that far, I got some of the cases and the cans and I began testing them, and found that there were difficulties that were quite unexpected; but my correspondent got a chance to get cans even cheaper—second-hand cans cheaper than the ones I offered him—and he didn't wait for me to sell them to him, but bought elsewhere, and before he got my letter (he had waited some time) he wrote me that he had bought cans elsewhere, and unless I could make those cans cheaper he guest he had enough. About that time I had come to the conclusion I was not going to send them to him, and I wrote back and said I was very glad to get his letter saying he had enough; if anything should happen that I half expected might happen, I didn't want to be a party to it. I think that happened some six or seven years ago, and only this year I got a letter from him, and he said, "There are a few of those second-hand cans that I bought, that you may remember writing me about and thinking they would be a good thing. Well, this is the last of them—I will never have any more. You know of some of the trouble I have had." He blames me now for being a party to that, because I suggested the thing. I had not investigated thoroughly before I communicated my thought to him. Now this is a warning to you who have not made any mistake up to this time. If anybody undertakes to use cans for honey that have been used for anything, if they don't get caught the first time, they are twice as liable to get caught the second time with trouble; and if they don't get caught the second time they are three times as liable to get caught the next time; and when they are caught, they are caught hard; they don't forget it. If I don't say anything or talk about anything else, I think I have helped ev-

everybody who will refuse to buy a second-hand can, no matter who offers it to them for sale, nor how good it is or appears to be. The package for honey ought to be tested, and the party who uses the package ought to know what conditions are necessary to keep honey in good shape. Take a man like Mr. France, he won't make a mistake with a barrel: he has worked out that thing. He knows now what is necessary to carry the honey in the right kind of condition, and it will keep for years in those barrels. Some years ago a bee-keeper came to this city and sold his honey to the retail trade. A good many have tried it in the past, but they have not all stayed with us; but this one came, and the first year he sold all his honey, and sold all his neighbors' honey, and bought quite a lot of honey from me. Well, he felt enthusiastic about the matter: he felt sure that he had gotten into a business now that he was going to get rich at. He didn't think anybody could do much better than he was likely to do, and then he did the first year. The second year he didn't bother much with his own product, but he bought from me several tons of honey and stored it, and it was mostly basswood honey in barrels. The second year he didn't sell nearly as much honey as he did the first, and the third year he didn't sell a great deal of honey, so little, indeed, that he concluded he would sell out the business. Some in the audience could probably tell something about that, too. That was his experience. I bought some of that honey back from him after it had been stored in the basement, I think, fully three years, and there didn't seem to be anything the matter with the honey: some hoops had come off from some of the barrels in that lot—not the lot I sold him—they had broken open, had burst the head out, or something; but I knew mine by the marks that were on. I sold them to other parties and the honey seemed to be all right. Barrels are dangerous unless the man who makes the barrel knows what it is for, and knows how to make a barrel to hold honey. A tin can that will hold a liquid and is well soldered, will do for honey on almost any occasion, altho a great many people who have made cans for honey solder the joints so tight that the honey has burst them open: the jarring has sprung them, and lots and lots of honey has been lost in that way. I have had them come in car-loads where the cases were thrown and smeared in honey 3 inches deep on the floor of the car. I don't know that I have anything more to say on this almost inexhaustible subject, for strong-minded people who have had lots of experience know what they need in their business in the way of a package, and as for selling it, we need small packages and we need larger ones. If they are all small, they will not bring any more than half large and half small; that is probably the experience of the trade.

Dr. Mason—Now, you see the persons who have spoken in this discussion might have summed the whole thing up by saying, Put your honey in the package that your market demands. It doesn't depend upon the barrel; it depends upon the man who handles the barrel; doesn't depend so much on the can as on the man who handles the can. Don't try to suit Mr. Abbott by sending honey to him in cans, if you have a market that wants barrels.

Mr. Poppleton—Mr. Burnett, how much more can you sell honey for in the Chicago market in cans than in barrels, on an average?

Mr. Burnett—I don't know as I can answer that question unless it is in this way. If it was about half in cans and half in barrels it might sell at about the same price.

Mr. Poppleton—Mr. Abbott said that we shippers should have a little compassion on the buyers. I want the buyers to have compassion on the shippers and pay us back the extra money cans will cost us, and they will get all the cans they want. It costs me 75 cents more per hundred pounds to ship in cans than in barrels. The whole question with me is that and that alone.

Dr. Mason—Mr. York spoke of the National Biscuit Company having so many cans to sell: we have a National Biscuit Co., in Toledo, and I ask them, "Why do you have so many cans to sell?" and they answered, "Because we can't get honey in barrels and are obliged to buy in cans."

Mr. Poppleton—I have taken great pains to find out what our market demands and they tell me barrels.

Pres. Root—Mr. Aikin wishes to make an explanation of the labels on packages.

Mr. Aikin—The explanation I wish to make about labels on packages is just this: Mr. York, or any other dealer, need not worry about losing his trade because my name and address is on the package. It is only the man who buys or ships in car-load lots who is able to pay freight, and a man in this city who wants to buy a case of honey,

either comb or extracted, isn't going to send to me and pay local freights. No, he is going to buy my honey from Mr. York. I wish to speak on that point because there is an undue fear in that respect.

Mr. York—There are many private families in Chicago who could easily afford to send to Colorado for Mr. Aikin's honey, and pay for it and also pay the freight on one 60-pound can or 50 pounds of comb honey, rather than pay the retail price that grocers have to charge here for honey. While such dealing direct with the producer by the consumer is entirely right, still no city retail dealer is quite foolish enough to furnish his customers with information as to his source of supply so they can buy direct. It costs too much to work up a demand or line of customers, to turn it over to some one else in that way afterward. I would not expect that the bee-keeper who buys honey of me to retail among his customers would use my name and address on his retail packages, and thus show his customers just where they can get that same kind of honey. That wouldn't be ordinary common-sense let alone business sense.

(Continued next week.)

Report of the Illinois State Convention.

BY JAS. A. STONE.

The Illinois State Bee-Keepers' Association held its tenth annual meeting at Springfield, Nov. 20 and 21, 1900. On account of bad Illinois mud roads there were but few present except those who came by rail. Nevertheless we had a good and profitable meeting. Among those present were President Smith, as he always is; Messrs. George W. York and C. P. Dadant, and, as Mr. York has already said in the American Bee Journal we heard with great interest of a few of the many things he (Mr. Dadant) learned while on his trip thru France, and other parts of Europe.

The treasurer not being present at the opening of the meeting his report was given along with the secretary's, and showed that on account of furnishing the Bee Journal to every member it left a small treasury.

After the reading of the reports a motion was made by Mr. Dadant that the one dollar membership fees go into the treasury, and the members pay extra for their American Bee Journal. Whereupon the secretary assuring them the treasury had need for but very little funds, the motion was withdrawn, and the same arrangements as in several years past were made, to give a copy of the American Bee Journal for one year to each person who sent in a dollar for membership in the Illinois State Bee-Keepers' Association, to Jas. A. Stone, Sec., Rural Route 4, Springfield, Ill.

The president's address was brief, but in happy, well-chosen words.

Mr. Becker said, "I am a Methodist, and favor experience meetings, so let us hear from all the members. My bees swarmed a great deal, and stored no honey. Mr. Dadant, how would you prepare a winter cellar for bees?"

Mr. Dadant—Our cellar is separated from the furnace-room by a double 4-inch wall, packed between with sawdust, ceiled overhead, and there packed the same. There are two windows outside, arranged with shutters to let in air but not light.

Mr. Titterton—Do you let your bees swarm, or do you divide them?

Mr. Dadant—Almost entirely the latter.

Pres. Smith—I prevent continued swarming by first hiving the second swarm in a new (fresh) hive, and at the end of 48 hours empty them in the evening at the entrance of the mother (old) hive, which will likely end swarming for that colony for the season.

Mr. Dadant—Whom did you get that from?

Pres. Smith—From you.

The premium list committee reported, and on motion a temporary committee was named as follows: Chas. Becker, C. P. Dadant, and Jas. A. Stone.

It was voted that the premium list committee be instructed to ask for a larger premium on honey extracted on the grounds, on account of its being an educator to those who were prejudiced against extracted honey.

Mr. Dadant said in his splendid talk on his travels thru Europe, that he could distinguish the American honey at the Paris Exposition from that of the other countries, by the neatness of the sections, even at a distance; and in the apiaries that he visited he did not see the improved implements that were to be found in this country. He began to think he was more of an American than Frenchman. But he also said in their favor that their bee-keepers' meetings

were more largely attended than ours, and they did not allow any one to enter their meetings till he had paid his fee, of one or two dollars, as the case might be, and still had a membership of 200 or 300.

Mr. Becker—One year, when the white clover honey-flow was good, I had one colony that gathered 16½ pounds of honey in one day, and the same colony in the fall gathered 14 pounds from heartsease.

A paper by George W. York was read as follows:

PURE FOOD LEGISLATION.

This is a large subject. It means much at both ends. First, it will take much hard work to secure it; and, second, it will take much more and harder work to enforce it after it is secured.

Illinois succeeded in the passage of what was thought to be a good pure-food law at the last session of its legislature. Some attempt has been made to enforce it in Chicago, but so far we believe without much effect.

As to the question of the need of pure-food legislation, only the adulterator or swindler would object. The very health and life of the people depend upon their getting pure food. There is also a moral aspect to the case. The sale of impure food is a deception and a fraud practiced upon the purchaser or consumer. It is getting money under false pretense, and a pretense of the very falsest and most dangerous kind. The state should protect the lives of those who help make up the State; especially should it step in and insist that helpless women and children shall be prevented from being imposed upon and defrauded by those who pretend to be their friends.

I think that if the law contemplated the prosecution and punishment of the manufacturer or wholesaler of the goods instead of the retailer, better results would be obtained. This would of course necessitate the labeling of practically all goods offered in the open market. But this could be done, and the retailer could be required to reveal the source of his supply, if found adulterated.

Another very important requirement to the successful results of pure-food legislation is honest officials—officers who know no better than to enforce laws just as they find them, without fear or favor. No law ever enforced itself, and never will. The reason, almost invariably, why prohibition doesn't prohibit is because of officials who don't officiate honestly and fearlessly. I believe, however, that the present pure-food commission of Illinois are all right, but that the fatal weakness is in the law itself.

But so long as the "dear people" persist in electing as their State lawmakers, saloon-keepers, pothouse politicians, gamblers and frauds, just so long may they expect to have weak laws—laws that fail at the most crucial time, because they were enacted with that intention. The people must act honestly and decently themselves in the selection of their lawmakers and public officers, then, and not until then, need they expect that good laws will be furnished and properly enforced.

It would be one of the simplest things in the world to drive practically all the adulterated honey out of the Chicago market, or any other market, for that matter, if it were gone about in genuine earnestness and with determination to accomplish the thing. There should be a provision in the law permitting the confiscation of all the adulterated food on the market. A few raids backed up with a law having such "teeth" in it would soon end the adulterating business. There wouldn't be any profit in it; and any business that is unprofitable in dollars and cents will soon be left to take care of itself, and that means speedy death.

The people should unite in demanding the enactment of strong adulteration laws. If present legislatures refuse to comply with such demand, then proceed to elect men that will give heed to the people's will. Having secured suitable laws, elect only such men to office as will understand that their retention in office depends upon their executing the will of the people as expressed in the laws. Pretty suddenly after such things have come to pass there won't be much adulterated stuff to be found. Even frauds don't enjoy frequent and close contact with so good a thing as a good, strong law—one with cross-stitch saw teeth that cut both coming and going.

GEORGE W. YORK.

The election of officers for 1901 resulted as follows: President, J. Q. Smith, of Lincoln; 1st vice-president, George Poindexter; 2d vice-president, C. P. Dadtant; 3d vice-president, S. N. Black; 4th vice-president, J. M. Titterington; 5th vice-president, George W. York; secretary, Jas. A. Stone, R.D.R. 4, Springfield; and treasurer, Chas. Becker.

On motion the temporary premium list committee was made permanent.

The convention then adjourned *sine die*.

JAS. A. STONE, Sec.

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

BEES GNAWING COMB FOUNDATION.

It is a vexatious thing to have bees gnaw foundation after it is put in—half inch of foundation, then a big hole, then the lower half of the foundation pretty much all right, except with nothing to hold it in place. Presumably Mr. Doolittle is right, that flat-bottomed foundation is gnawed much the worse; and that is a serious short-coming. Still, it may be rather the thinness than the shape that tempts them. When they are fixing the bottoms they don't tear things down, and when they tear down they are not fixing the bottoms—not even thinking whether bottoms suit them or not. I don't think bees ever nibble up foundation at the same time when it is being prepared to put honey in, or that they ever throw the fragments away, as one might expect. Incapable of entertaining more than one idea at a time, and anxious not to be idle, they rasp it up to mix with propolis and daub things with. My bees won't even spare the half inch at the top when only starters are put in.

And prepare your queenless hive to keep your drones, while you have plenty. For if Doolittle can't practically make bees rear more in the fall it isn't likely that you can. Hand-picking of drones I am rather suspicious of. May be it's all right. Almost certainly it's no harm. One can't get rid of the idea, however, that the really valuable inheritances (prospective) which drones carry about them inevitably must be totally invisible—or mostly so. Page 7.

THE GREED OF GREAT CORPORATIONS.

I think we have been shown few examples of the *tempt* with which great corporations regard what common citizens think, and *must think*, of their ways, to exceed the one given on page 9. Freight to San Francisco charged when the goods never went there, and were never intended to go there, and then freight back again added in—a regular add-insult-to-injury kind of clean steal. I'm not sure we are going to have overcharges corrected right away, for when there is a desire to overcharge, some less flamboyant way to do it than that can easily be found; but I'll venture to prophesy that the twentieth century will not be very many years old before corporations decide that it pays to keep their *outrages* a little out of sight of the people when they can just as well as not. Presumably the evil habit complained of grew up in the first place by small packages being actually sent that way—nobody on the thru trains knowing what the locked cars contained in the line of small items.

CHUNK HONEY IN PAILS.

That chunk honey on page 19 was too big a lot, and had "got too far from Canada." People used to sections are not likely to evolve backward and buy the old-fogy style. But in back-country towns, where folks have never bought sections, and don't want to begin, there small lots in bulk would be all right. I doubt if it's best to solder it up in tin, however. Empty candy-pail, or something in the line of a big pail with close-fitting cover, would look to me more like the thing, even if it had to go 50 miles by wagon. Indeed, with modern goods the freight and breakage of half a ton of honey might easily pay for lots of wagoning.

HEXAGONAL APIMARY A BACK NUMBER.

I weep over Mr. Doolittle giving the weight of his name and example to the hexagonal style of placing hives. Out of date for one thing, and, for another thing, not much to recommend it in the first place, but the fantastic resemblance of the hexagon to the honey-comb. The fact that we are bee-keepers does not make us long to be paid for our crop in hexagonal money. Hexagon not even as good as the rank-and-file, and the latter barely escapes being a dis-

grace—confuses the bee, while the hexagon confuses both bee and keeper. Page 20.

OLD GRIMES AND PERFORATED METAL.

Old Grimes again, eh? Well, well! Poetry has no power to fulfil itself, evidently. And isn't he slandering our craft where he says that few of our extensive bee-keepers use perforated metal? May be he's right, tho. 'Speets, in that case, that the executors of our new pure-food law will get around to their cases sooner or later, and treat them to a jolly fine for putting honey on the market that is mixt with larval food and juices—and three cheers for the pure-food law! Page 20.

Questions and Answers.

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Feeding Bees in Winter.

I have a lot of bees that will need feeding. I read of bee-candy. Where can I get it? and how is it fed to the bees? I have old-fashioned hives without sections. Would it do to put the candy underneath, or how will it be best to use it?

SUBSCRIBER.

ANSWER. It may be you can get bee-candy from dealers in supplies, but each bee-keeper generally makes it for himself, and you will find instructions for making in your text-book. [See page 59 for directions for making the "Good" candy.—EDITOR.]

From what you say, your hives are probably box-hives, and there is no chance to feed them above. If the weather is such in your locality that bees are flying every few days, it will be all right to put the candy underneath. Crowd it close up to the combs, so the bees can crawl directly from the combs upon the candy. Put the candy there in the evening, and contract the entrance for a few days, so the robbers will not trouble. If you are in a cold locality, where bees may not be flying for some time, take your bees in the cellar if they are not there already, turn the beehive upside down, and lay the candy on the combs.

How Many Bees Die During Winter?—Wintering in a Warm Room.

1. How many bees in a good colony will die during the winter months, or before the flowers come in the spring?

2. I have two colonies in a room upstairs, which is heated from the kitchen stove. The bees were placed there because their storehouse of honey was not sufficient to carry them thru. Should they be kept in darkness, or have the light? I have a glass box over them, so they can fly around a little, and also carry out the dead bees. Some think they will not winter in this way, but they seem to be doing well, and are quite ambitious. NEW YORK.

ANSWERS. 1. It is a hard thing to give a definite answer. One colony may lose ten times as many as another, the two sitting side by side. A given colony may lose ten times as many bees under unfavorable conditions as it would under the most favorable conditions. One colony may be composed mainly of old bees whose "span of life is nearly run," another may have a large number of young bees. So you see it's a hard matter to say how many will die, and it's no great wonder that the books don't try to tell us. About as near a definite answer as they could come would be to say, "A whole lot." If I were forced to give some kind of an answer, I think I should say at a guess, that you ought not to complain much if not more than half of them died, and feel exceedingly thankful if only a fourth of the colony died.

2. Look here, my good friend, if that colony comes out alive in the spring, you can be put in a glass case in a museum and exhibited as the man that brought thru the winter alive a colony of bees in a room well warmed and

lighted, the bees having the opportunity to fly within a limited space when they had a disposition to do so. It is true that some cases have been reported in which bees have been successfully wintered in a warm room above ground, but as a rule it is considered that in such a room kept dark thruout the winter, a colony of bees will be found dead in the spring, and if the room is light they will be dead yet. It might be well for you to darken the room, give the bees some honey or candy, and in two or three days later return them to the cellar.

Wintering Troubles.

I wish you would tell me what to do with my bees. For awhile the temperature was at 42 degrees, and one of my colonies started to rear young drones and consumed their honey. They had a young queen which I could not get to lay last fall. I fed them for a week, and it didn't do any good, so I thought I would unite them in the spring, but as they used up most of their honey I just took the cover off and the bottom-board of another that had plenty of honey, and gave them a little tobacco-smoke, but this did no good. There was about two quarts of dead bees in a few days. I don't know whether the smoke killed them, or whether they killed each other. Then, the temperature went down to 35 degrees, and my bees were all quiet. But now it is down to 30 degrees, and they are making a little noise.

IOWA.

ANSWER.—Probably about all is done that can be done. The colony that began rearing drones was most likely queenless, or had a bad queen, being worthless in either case, and was killed by the bees that had a good queen. The bad colony is now dead, for which you need not greatly mourn, and the other colony may be little the worse for the scrimmage.

Feed-Bags and Burlap for Packing.

How will old feed-bags or burlap do for packing outside cases, 5 or 6 inches larger than the hives? I have only 3 colonies this winter packt with burlap and with hay-chaff in outside cases, and a super under the hive for a space below. MAINE.

ANSWER.—They will make good packing, but look out that the mice don't find it too comfortable a place for their nests.

Bees Troubled with Moth-Worms.

What can I do to stop millers from getting into the hives and destroying the whole colony? I have had five colonies to share the same fate. They seem like the common little white millers, and then there are worms, some an inch long. They are packt in like sardines in a box. Father had bees for 50 years, but never had anything like this. As he is not here to teach me about bees, I will have to depend upon the books. NEW JERSEY.

ANSWER.—When worms spin their cocoons in a hive and are packt like sardines in a box, the case is pretty bad. The first thing, however, that it is important for you to get into your head, is that the worms are rather a result than a cause of the trouble. In a strong colony of bees, the worms never get much of a foothold, for the bees will keep them cleaned out without any attention on your part. A weak colony of black bees may allow the worms to get in, but if the bees are Italian even a weak colony will keep the worms at bay. You may give the bees some help by lifting out the combs and picking out the worms with a wire-net. Aside from this about all you have to do is to see that no colony becomes queenless or weak, and to try to have as much Italian blood in your bees as possible.

The Chicago Convention Picture is a fine one. It is nearly 8x10 inches in size, mounted on heavy cardboard 10x12 inches. It is, we believe, the largest group of bee-keepers ever taken in one picture. It is sent, postpaid, for 75 cents; or we can send the American Bee Journal one year and the picture—both for \$1.00. It would be a nice picture to frame. We have not counted them, but think there are nearly 200 bee-keepers shown.

The Premiums offered this week are well worth work ing for. Look at them.

Three Foggy Notions of Value.

Wide-Frame Supers, the Honey-Board, and the Telescope Hive-Cover.

BY FRIEDEMANN GREINER.

WHAT wonderful improvements have been made during the past 50 years in bee-hive manufacture! Even 30 years ago it was an uncommon sight to see anything else but box-hives in a bee-yard. If we will expect an occasional hive of an extremely odd pattern, box-hives were the order of the day. A market change has taken place—a change for the better. Well-made and nicely painted movable-comb hives have taken the place of the ugly boxes. It would seem almost as tho the climax in the line of hive-manufacture had been reached; but still the improvement is going on. As to the construction of the brood-chambers little is left that need be changed. Of the several different patterns, one should please the most existing.

As to a cover for my hives, I can not become reconciled to use the modern light single-board or even the improved ventilated covers. A single thickness of lumber between the inside fixtures and the weather is certainly not enough, and if a shade-board is required to make it safe—and it is—a better cover could be built, not costing more. Accidentally I once left the telescope-cover off from a hive during the noon hours, leaving the surplus-case protected only by a $\frac{1}{4}$ -inch board. Two hours later, when I happened along again, the honey was running out of the entrance of that hive, and a case of honey was ruined. A shade board would have prevented that loss. A regular telescope-cover, such as Father Langstroth used on his 10-frame-portico-hive, would have been still better. I have not yet found anything to suit me better. I think it is an advantage to have the cover made tall enough at least to take in one super. If made to take in two supers the cover becomes too heavy and expensive. It would, of course, be a good thing to have the two supers well-protected against loss of heat as well as against extreme heat; but if we do not have better honey seasons than we have had for two or three years, the single-tier cover will suffice.

The honey-board is the next foggy notion. Father Langstroth made use of it; and in this way it was handed down to me. When I saw so many adopt and use the quilt instead, I also gave it a trial. For two years I used it extensively, but it did not please me as did the board, and I discarded it for summer use. The bees have a non-commendable way of chinking in propolis between the quilt and the tops of frames or sections, and every time the quilt is raised more glue is crowded in, for the quilt cannot well be readjusted as it had been before. More propolis and stain is found on quilt-covered sections than on those entirely exposed. I would rather use the board, even on such supers as have their sections unprotected at the top. A honey-board is also very convenient as a record-keeper. On many of my hives the record for 10 years may be found on the honey-boards.

A marvelous progress—I would rather say change—has been made in the supers, and most complicated arrangements have made their appearance. Quite a number of years ago, soon after Mr. Root invented his double-tier wide frame, my brother and self hit on the same device unbeknown of what Mr. Root had already in use, except that we adopted a single-tier wide-frame and wooden separators. I have since, and before, used other styles of supers quite extensively, but I have not been able to find one that meets all my requirements and is as handy as this one. To be sure, I have changed the size of my sections several times, but still the wide frame is my favorite.

The objection is sometimes raised that it is difficult to remove the filled sections from the frames. Those who have never given the wide frame a trial are excusable for holding such an opinion. A friend from a neighboring town stopped with me this fall and looked over things; he expressed just such fear. He was not in the business very extensively, but said he wanted to go in, and before doing

so he wanted to find out what the best supers and appliances were, so not to be obliged to change later on when it would cost more to change. (If we all had been as careful as this friend, how many mistakes would have been avoided, how much money we might have saved!)

Well, it so happened that I did have a few full cases of honey on hand that had not been disturbed, but were exactly as they came from the hives. They were opened up and in a few moments the doubts and fears of my young friend were dispersed, for the filled sections came out easier than empty ones would. In fact, there is no difficulty whatever.

And then the advantage of having our sections protected on all sides is not well to be sucered at. The so-called section-holders, the T and other supers, leave just that part of the sections exposed that, *above all*, should be protected. I always ease my honey the same side up as it was in the hive; thus the tops of the sections are first exposed to view when a case is opened, and, when they are soiled, they make a bad impression. I can understand that those who use such supers as allow the soiling of the section-tops have use for sand-paper machines. I find I can well dispense with them as I seldom use other than wide-frame supers.

In conclusion I wish to say: It is true that when we become accustomed to certain implements, or the ways to use them, we gradually become of the opinion that those implements or methods are superior. The bee-keepers in Germany, for example, use a hive accessible only from the rear; their hives more nearly represent a cupboard; grooves are cut out in the proper places to allow two, three, or even four sets of frames to hang one above the other. The German bee-keepers understand how to get along with the inconvenience of their hive, and altho they well know what kind of hives we in America use, not one in a thousand can be induced to try them. We Americans can hardly understand this attitude of the Germans; and yet, even in America, it takes a long time, sometimes, before a good thing is recognized. Sometimes even a good thing is thrown aside, as is the case with the wide-frame super, the honey-board, and the telescope cover.

Ontario Co., N. Y.

An Interesting Cellar-Wintering Experience.

BY E. S. ROE.

I KEEP my bees in the cellar, and have a lamp-stove to regulate the temperature during extreme cold spells. The cellar has no other deposit than the bees. The lower hives are about two feet above the floor, but otherwise so compact that only narrow aisles are left between the tiers.

Yesterday (Dec. 31) the mercury registered, outside, 28 degrees below zero; in the cellar the temperature was 2 degrees below freezing. So in the evening the lamp-stove was arranged on the ground floor, as I had done a few times before, with a metal cover over the top for shading. The light coming from under the burner seemed to annoy the bees more this time than before, so a cheese-mould (zinc open at both ends, and its sides perforated with small holes) being close at hand was placed around the lamp. The free draft at the top and the small holes in the sides I thought would give plenty of oxygen.

After watching the "dummy" a little while, with an air of satisfaction, I turned from the cellar, replenished the fire in the heater, and prepared for the pleasures of dream-land.

I will never be able to tell how much I dreamed, but at any rate just as the Old Year and Old Century were leaving, the bees and I were undergoing a very unpleasant siege of lamp-black smoke. The strong scent awakened me, and on lighting a match I noticed it was just a little past 12 o'clock. The New Year and New Century were here, and the house full of smoke—"a bad beginning"—but there was comfort in the last part of the saying—"a good ending."

The stovepipe was examined, and then the stove. The trap-door leading to the cellar was next, and the trouble found. The lamp-stove was all aglow. Flames were shooting from under the burner. A little red "vase" stood flaming from the perforations of the screw cap of the lamp, and a column of smoke was rapidly moving from the top. The blaze was soon put out, and with a cloth I was able to hold the hot and sputtering thing long enough to remove it.

The bees were surprisingly on their best behavior. Only one or two were heard flying. The hive entrances

and covers of the top hives were covered with flakes of lamp-black. They had been carried up by the heat and then settled on the hives like falling snow. Of course, the use I made of the cheese-mould was the cause of the trouble. The heat being more confined caused the light to burn higher, which in turn generated the more heat, keeping the flame on the increase, in this way acting on a principle of law that was rapidly carrying it to a serious condition—possibly to the end of explosion, loss of bees and house.

Each reader will be left to form the moral that will be of some practical good. I am thankful that smoke accompanied the excessive heat and came to notify me of the danger.

To-day the bees are quiet, and I hope they are as they seem—no worse for the experience.

Todd Co., Minn., Jan. 1.

Contamination of Queens Thru Hybrid Bees and Royal Jelly.

BY G. M. DOOLITTLE.

I HAVE two colonies of hybrid bees in an isolated position, with which I wish to try an experiment. I wish to have them rear some queens from Italian larvae by the plan given in your book. Now, if I supply the cell-cups with royal jelly from a hybrid colony, place larvae in them from a pure Italian queen, and place these prepared cups in a hybrid colony for completion, will the queens emerging therefrom be pure Italian? Be kind enough to reply to this question thru the American Bee Journal, as I am a regular subscriber to that excellent paper." Thus writes a correspondent.

In answering the question, I will say that I take it that the questioner is in doubt about the part played thru the bees which prepare the food for the queen-larvae. He has evidently heard, thru some one having "locks hoary with age," something of the old theory that was put before the bee-keeping fraternity during the sixties, of "like food, like queens." As hybrid bees are used, quite likely, they giving the best results in queens of any variety of bees with which I am acquainted, except the Cyprians, I have and do use them very largely to feed and perfect queen-cells, and, after years of careful watching, and with years of success in perfecting Italian bees, said to be as good as can be found in the world, I fail to find wherein the food has anything to do with purity of stock, or the changing of the color, or the disposition of the progeny of any queen, in the least.

If royal jelly prepared by black or hybrid bees could contaminate queens of the Italian race, surely the same food prepared by Italians which were of such an orange color that they seemed like lumps of gold when flying in the sunshine, would contaminate the black or German race of bees. And I have proven, beyond a doubt in my own mind, by several experiments, that black queens brought to perfection thru the royal jelly prepared, and the nursing given, by the yellowest of the golden Italian bees, are not in the least degree different from those nursed by their own "blood," hence I feel that I am justified in going on record as saying that the queen progeny of any race or variety of bees are in no way changed as to markings, disposition, etc., thru the food given them. If there are those among the readers of the American Bee Journal who think otherwise, I should like to have them tell us upon what they base their conclusions. While these nice points are of interest only to queen-breeders, in a dollar-and-cent way, yet they are helpful in making up the general fund of bee-knowledge which we are handing down to future generations; hence I believe the American Bee Journal will be willing to give all of the best thoughts on the matter which may be sent in.

But before closing I wish to say a few words about that purity part which our correspondent seems to cling to, as being the *ne plus ultra* in the Italian race. I have objected for years, and do still object, to the calling of our Italian bees or queens *pure*, for, from everything I can gather, they are nothing but what would be properly called a thoroughbred variety of bees. This is also proven by the fact that we have all shades and colors of these bees, from those having golden abdomens nearly their whole length (as shown in the workers), to those which are so nearly black that it takes an expert to tell whether they have any Italian blood about them, only as it is known that they were imported from Italy—the very same place from which came the pro-

genitors of the most beautiful orange-yellow bees obtainable in this country. Had the Italian bees been pure, in a sense equal to that of the pure black or German bee, no such change of color could possibly have come about by years of breeding for color. But this non-purity part of the Italian bee in no way detracts from its standing at the head of all of the bees, as to its industry and usefulness to mankind.

Onondaga Co., N. Y.

The Coming Season in Southern California.

BY PROF. A. J. COOK.

AS the bee-keeper of Southern California is so much interested in the rains of the season, the statistics of the present winter will be of interest. It has been held generally that 15 inches of rain insured a good honey crop, and was necessary to a maximum yield of honey. Doubtless the way the rain comes has much to do with this. Last year a rainfall of 10.05 inches gave a fair honey crop in some sections, while the 11.5 inches of two years previous gave no crop at all. We have already had 12.89 inches this season. We had 9.36 inches before December, mostly in November. Early this month we had 2.68 inches, and we have just had .85 inches, with the weather still unsettled. This has been so evenly distributed that we may hope for great things from it. The season is hardly more than half gone. Our average is about 16 inches.

I give here the rainfall at Claremont for the past nine years, from 1891 '92: 12.54; '93 '94: 11.17; '94 '95: 9.58; '95 '96: 11.05; '96 '97: 7.87; 10.65. Los Angeles Co., Calif., Jan. 21.

LATER.—Jan. 28.—I wrote you last week regarding the hopeful outlook for the coming season, for the bee-interests of Southern California. Since writing you we have had a nice rain of nearly one-half inch, which has raised the total over 13 inches. We are now having a much better rain, the amount of which I have not yet learned. But as it has been quite steady for the past 18 hours I think our total must be above the average of 16 inches. And our season is not yet half over.

The rains have come in such gentle mood that nearly all has been retained in the soil. This not only rejoices the bee-keepers of Southern California, but is equally cheering to the grain-growers (who have not had a full crop now for several years), and to the fruit-growers. Our friends of the orchard have not suffered so severely, because of the discovery of the immense reservoir beneath us, yet they, too, are deeply interested, as pumping is quite expensive, and all will breathe more freely if the great underground reservoir is again fully replenished. A few years ago we had here in Claremont a large number of splendid flowing wells. But the prolonged and unusual drouths, together with the excessive pumping, has made it necessary for the last few years to pump all these same artesian wells. It would give great satisfaction if these wells should again commence to flow. I think Southern California has promise of an exceptionally prosperous year.

A. J. C.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

A WHOLE GARDEN For 14c.

We wish to earn this year 20,000 new customers, and hence offer:

1	1 Pk. Salzer's Blue Javel, Tomato.....	1c
1	1 "The Northern Lemon.....	1c
1	1 "Nana's Favorite Onion.....	1c
1	1 "Lambert Green Cucumber.....	1c
1	1 "Early Garden Beet.....	1c
1	1 "Early Cauliflower.....	1c
1	1 "Late Rose Market Lettuce.....	1c
1	1 "Elegant Flower Seeds.....	1c

Worth \$1.00 for 14 cents! \$1.00

We will mail you this entire Garden worth of splendid seed novelties free, together with our large illustrated Plant and Seed Catalogue on receipt of this notice and 14c in postage.

Choice Onion Seed 60c lb and up.
Potatoes at \$1.00 per barrel and up.
Cauliflower alone, 50c lb.

SEED POTATOES
\$1.50 a Barrel and up.

Mexican Northern Grown are always the best. 20 best varieties. Highest proof, enormous yields, highest quality, lowest prices. Sold in any quantity, one pound to a car load.

At catalogue free on request.

Harry R. Hammond Seed Co.
Box 2, Bay City, Mich.

Largest growers of seed potatoes in America.

Low Rates West and Northwest.

On Feb. 12th, and on each Tuesday until April 30th, the Chicago, Milwaukee & St. Paul Railway will sell one-way second-class tickets at the following very low rates:

To Montana points, \$25.00
To Nor. Pacific Coast points, 30.00
To California, 30.00

These tickets will be good on all trains, and purchasers will have choice of 6 routes and 3 trains via Missouri River each Tuesday. The route of the Famous Pioneer Limited trains, and the U. S. Government Fast Mail trains. All ticket Agents sell tickets via the Chicago, Milwaukee & St. Paul Railway, or for further information address F. A. Miller, General Passenger Agent, Old Colony Building, Chicago. 6A3t

on page 809 (1900), "Was sugar in the urine caused by honey?" Being affected in the same way, the doctor said the same thing, "You have eaten too much honey." Now, Doctor Miller, will honey really cause diabetes? I stopt using sweets, and after six months' treatment the specific gravity was 29. I am now using saccharine to sweeten my coffee, but find that it raises the specific gravity to 26. Galen Institute says, "Eat honey if you crave it." I did one evening, and the next morning the specific gravity was 29.

Experience With a Clipt Queen.

I would like to tell of an experience I had with a swarm of bees that had a clipt queen. They came off, flew around awhile, then went back and clustered on the front of the hive up under the shade-boards, staying there eight days. Soon another swarm came out with a young queen and clustered, and I lived them. Two days after this the old queen came out with a swarm, and the swarm on the front of the hive rushed after her, altho they had not moved when the other swarm came out. I moved the old hive from the stand, put a new one in its place, with the caged queen on the alighting-board. The swarm came back, entering the hive with the old queen. Why did the old queen come off with the last swarm? EDWARD KNOLL.

Ontario, Canada, Jan. 25.

Not a Good Season—Yellow Wax.

The past season was not a very good one for bees in this locality. Last winter and spring were very hard on them, and I lost over half of mine, and did not have a swarm during the season. The bees stored very little surplus honey during the forepart of the season, but thru August and a part of September they did pretty well. I secured nearly 100 pounds of surplus honey, and have put 10 colonies into winter quarters, one of which I am keeping on shares. This colony is from a hive of bees that had been on the farm of their owner for over 90 years, having been brought there by his father. Bees have been kept on the farm which I have, since 1836, without intermission. In the fall of

2-4a3t

1874 I had 7 colonies and father had 23, and in the spring I had none and he had 7. I bought a couple of colonies and in the fall of 1878 I had nine colonies and father had 36, but by the next spring I had none again, and father had only three.

I have an old log-gum in which my grandfather brought a colony of bees to this farm in 1821.

In regard to yellow wax, a good plan for those who use wax-extractors is to let the melted wax run from the extractor into a pan of hot water. This will give the wax a chance to cool slowly, and the impurities will settle to the bottom of the pan.

I began taking the Bee Journal in January, 1883, and have nearly every number since that time, and I like it. J. S. BARE.

Trumbull Co., Ohio, Jan. 15.

Short of Stores Sour Honey.

My bees are short of winter stores—shortest they have been in 18 years—and are trying to rob. The short crop was caused by too much rain during the past season—two weeks in April, all of June, until July 3d, and nearly all of October.

I purchased a lot of willow and popular extracted honey at a sale, and found that it had been extracted before it was ripe, and it is slightly sour and granulated. Can you tell me to what degree to heat it in order to reduce it to a liquid state? JOHN M. RYAN.

Marshall Co., Ala., Jan. 8.

[Try 160° or 170° degrees. But don't let it stand at that for any length of time, as there would be danger of changing the color of the honey by almost burning it.—EDITOR.]

Getting Outside Sections Filled—Robber-Bees—Leaky Covers.

I can not report a very good crop for 1900 owing to the drouth. The white clover crop was cut short in June, so the bees could work on it only three weeks. I secured 1250 pounds of fancy clover section-honey, which I think was pretty good from 43 hives in three weeks. Owing to the honey-flow being cut off so short the bees did not swarm.

I have tried the plan spoken of by Mr. Thompson in the Bee Journal, to get outside sections filled as well as the center ones. For the last six years I have practiced putting empty bait-sections to the outside of the super, and I find that it works fine.

When one is bothered with robber-bees about the hives coal-oil is a good thing to use. Wet a cloth with coal-oil and rub it along any crack or crevice the bees are trying to enter—for instance, under the lid—and every robber will leave. I contract the entrance to any hive that robbers are bothering, and place a rag wet with oil where the robbers will smell, or better still, touch it, and they don't pass a second after smelling the oil. I never leave the rag very long after the robbers have gone.

I see quite a little in the bee-papers about leaky covers. I have hives in the home apiary that have been in constant use in the weather for 18 years, and not a single leaky lid in the apiary. Whenever a lid checks, take a good quality of shingles, paint them well, then shingle the cover; and all

Fred W. Muth & Co.

FRED W. MUTH, CHARLES J. HAUCK, P. W. J. HAUCK.

One Minute, Please!

We beg to announce that we have gone into the bee-supply and honey business. Being practical bee-keepers who understand the supply business thoroughly, and know pretty well the wants of the bee-keepers, the first thing we give is exclusive attention to the bee-supply business and the promotion of the sale of honey in this vicinity.

After visiting all the important manufacturers, we have selected a line that will give the best of satisfaction. Our location—adjoining the Suspension Bridge—is most central, and being only four blocks south from the Fountain Square, is right down in the business part of the city, and especially handy for our Kentucky friends, our facilities for prompt service are perfect; and our prices are consistent with good business judgment. Our CATALOG has many new things. Send us your name so we can mail you one.

the better if you give them a good dose of paint afterward. This kind of a cover will outlast a new one. If the lids are flat nail a cleat lengthwise down the center, shave the corners of the cleat with a plane, also the edges of the cover—that is, the eaves; then shingle as you would a gable cover, and you will have a small air-space left under the shingle cover, which makes a cooler cover in hot weather. The cleat can be one, or even two, inches thick.

EUGENE HAMBAUGH, Brown Co., Ill., Jan. 8.

Past Season a Failure.

I have been in the bee-business three years, and the past season was almost a complete failure. I will have to feed some of the bees to bring them thru the winter. But I don't see how I can do without the American Bee Journal.

ERNEST E. BAKER, Wayne Co., Iowa.

Bees Having a Flight.

To-day is warm and nice, and my bees are having a fine flight. I can't keep house (and bees) without the "Old Reliable."

H. W. CONGDON, Hardin Co., Iowa, Jan. 14.

Good Season—Honey From Spanish-Needle.

This has not been a very good year for my bees. I got only 3500 pounds of extracted honey and 50 pounds of comb honey from 60 colonies, which is not nearly so well as they have done in years gone by.

I am wintering them outdoors. I made a box with three sides, leaving the front open. I used clover chaff for packing as it absorbs the moisture; they seem to be doing very well.

I move my bees every fall to the swamps of the Illinois River bottom, in order to get the honey-flow from Spanish-needle. I had 40 colonies down there last fall, and secured 1500 pounds of as fine yellow honey as I ever saw.

JAMES GROVER, Brown Co., Ill., Jan. 15.

Difference in Color of Wax.

Did any of the readers ever notice the difference in color between wax rendered from old brood-combs and that rendered from honey-combs? Invariably when melting honey-combs—that is, combs free from cocoons—I get a pale-yellow-nearly-white wax, while if melting old brood-combs I secure a rich-yellow, first-class article. It seems Mr. Hutchinson's experience has been the same. He says he is unable to say what causes the difference in color, and I am not sure that I know what causes it, but I am sure that by careful experimenting the cause can be found. Is it possible that brood-rearing colors the wax thru and thru? I think not. I believe it is the stain from the cocoons that gives the wax from the brood-combs its rich-yellow color. We can tell in this way:

Melt up enough old brood-combs to get quite a lot of cocoons and residue; take some new comb and put above the pile of cocoons so that the melted wax will not run thru it. Of course a solar wax-extractor must be used.

My reason for thinking that the

stain from cocoons is the cause of the rich yellowness of the wax rendered from old combs is: If an old comb is put into water it turns the water coffee-color. Is it not reasonable to think that wax would be likewise affected?

W. T. STEPHENSON.

Massac Co., Ill.

Poor Season—A Bonanza in a Bee-Tree.

I lost my strongest colony last spring by neglecting to enlarge the entrance when I put them away the previous winter. One colony balled the queen, so I united it with another, which left me with eight colonies, some of which I had to feed.

I sowed two acres of mustard in the spring, and the bees built up strong, and commenced to swarm about June 3d. Four colonies swarmed, and then the mustard played out, and basswood failed, so they did nothing more until buckrush bloomed, when they stored a little surplus, but I got only 60 pounds of surplus honey for the whole season.

I sowed three acres of buckwheat, and there were acres of heartsease and other wild flowers, but the bees did not seem to store any honey from them. We had four severe hail-storms, which might account for this.

I helped to cut down a bee-tree last fall, and it was the sight of a lifetime. It was a very large tree, and I think the bees must have been in it about 4 years. The combs were a little over five feet long, and from 11 to 13 inches deep. Some of the honey was granulated; we got all we could stack into a wash-boiler, and a dish-pan full, besides—I should think about 125 pounds in all. I lived the bees, and fed them up, and now have 13 colonies in the cellar, which I think are in fine condition.

LEWIS LAMKIN.

Woodbury Co., Iowa, Jan. 18.

A Reliable Concern. Every live and enterprising business institution seeks by all legitimate means to increase its business. In this respect the publishers of newspapers are no different essentially from other men. It transpires therefore that we are ever on the alert for new business and always diligently seeking new advertising patrons. While this is true it however affords us an infinitely greater amount of pleasure to realize that we merit the continued patronage of an old customer. We are led to refer to this matter by the re-appearance in our columns of the Elkhart Carriage & Harness Mfg. Co. of Elkhart, Ind., whose advertisement will be found on another page of this issue. These gentlemen have long been known and are well known to our readers as the manufacturers of good and reliable goods, and for their honest and upright business methods. We take pleasure in again recommending them to our readers.

Storrs & Harrison Company.—Reliability is of the utmost importance in the purchase of trees and seeds. It is a waste of money to buy the kinds that won't grow. The Storrs & Harrison Company, Mansfield, Ohio, have been in the business almost half a century, enjoy an enviable reputation for accuracy and honesty, and any of our readers in want of anything in the nursery line should send for their valuable catalog for which no charge is made. Kindly mention the American Bee Journal when writing.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Jan. 19.—Honey is selling slowly; this applies to all grades with the exception of white clover and basswood comb honey, which sells readily at 10c providing it grades No. 1 or better. All other kinds of white comb honey sell at from 14¢ to 15¢, and candied wax comb at from 8¢ to 10¢; travel-stained and off-grades of comb, 13¢ to 14¢; amber, 12¢ to 13¢; amber extracted, 7¢ to 7½¢; dark and buckwheat comb honey, 10¢. Extracted, white, 7½¢ to 8¢; dark, 6¢ to 7¢; and white clover bringing the outside prices; buckwheat and other dark grades, 6¢ to 6½¢. Beeswax, 25c. R. A. BURNETT & Co.

KANSAS CITY, Jan. 22.—Fancy white comb, 15¢ to 17¢; amber, 13¢ to 14¢; dark, 10¢ to 11¢; demand good. Extracted, 7¢ to 7½¢; demand quiet. Beeswax, 26¢ to 27¢.

W. R. CROMWELL PRODUCE CO., Successors to C. C. Clemons & Co.

BUFFALO, Jan. 17.—All kinds of honey are so quiet it is difficult to make a sale. Occasionally some sells, fancy 14¢ to 15¢; few, 10¢; choice and 10¢ to 12¢; 15¢; few, 14¢; but dark, 9¢ to 10¢, and all grades in liberal supply. Demand for white honey is recognized. Extracted, 7¢ to 8¢, and not wanted in Buffalo. Beeswax, 22¢ to 27¢.

BATTERSON & CO.

ALBANY, N. Y., Jan. 18.—Honey market is dull on all grades now, with light stock and light demand. White honey comb in good condition, but not wanted. 15¢ to 16¢; 14¢ to 15¢; but not wanted. 15¢ to 16¢; 14¢ to 15¢. Extracted, white, 8¢ to 8½¢; mixt, 6¢ to 6½¢; dark, 5¢.

H. R. WRIGHT.

BOSTON, Jan. 18.—Fancy No. 1 white in cartons, 17c; A No. 1, 16c; No. 1, 15¢ to 16¢, with a fairly good demand. Absolutely no call for dark honey this year. Extracted, white, 8¢ to 8½¢; light amber, 7½¢ to 8¢. Beeswax, 27c.

BLAKE, SCOTT & LEE.

CINCINNATI, Jan. 16.—Market very quiet. No change in prices. Fancy white comb sells for 16c. Extracted, dark, sells for 5½¢, and better grades bring 6¢ to 7¢. Extracted, white, 8¢ to 8½¢. C. H. W. WEBER.

NEW YORK, Dec. 22.—Fancy white, 15¢ to 16¢; No. 1, 14¢ to 15¢; white 12¢ to 13¢; amber, 12c; buckwheat, 10¢ to 11c. Extracted in fairly good demand at 7½¢ to 8c for white, and 7c for amber, off grades and Southern in barrels at from 6½¢ to 7c per gallon, according to quality. Not much demand for extracted buckwheat as yet. Some little selling at 5¢ to 6c. Beeswax firm at 28¢ to 29¢.

Demand continues good for comb honey; supply fairly good. Extracted in fair demand with enough supply to meet requirements.

HILDRETH & SEGELKEN.

DETROIT, Jan. 19.—Fancy white comb, 15¢ to 16¢; No. 1, 13¢ to 14¢; dark and amber, 12¢ to 13c. Extracted, white, 7¢ to 7½¢; amber and dark, 6¢ to 6½¢. Beeswax, 26¢ to 27c. M. H. HUNT & SON.

SAN FRANCISCO, Jan. 9.—White comb 13¢ to 14¢; amber, 11¢ to 12½¢; dark, 8¢ to 9c. Extracted, white, 7¢ to 7½¢; amber, 6¢ to 6½¢; 7½¢; amber, 5½¢ to 6c. Beeswax, 26¢ to 27c.

Stocks of all descriptions are light, and values are being as a rule well maintained at the quoted range. Firmness is noticeable, and pronounced on light amber and water white honey, the latter being in very scanty supply.

HONEY MARKET.—We may have a customer within a short distance of you who wants our honey or beeswax. We are in close touch with all the markets; therefore write us regarding your crop, stating quantities, and we will quote cash price. References—Either Bank here for any business man in this city.

The Novelty Pocket-Knife.

Your Name and Address on one side—Three Bees on the other side.

[THIS CUT IS THE FULL SIZE OF THE KNIFE.]

Your Name on the Knife.—When ordering, be sure to say just what name and address you wish put on the Knife.

The Novelty Knife is indeed a novelty. The novelty lies in the handle. It is made beautifully of indestructible celluloid, which is as transparent as glass. Underneath the celluloid, on one side of the handle is placed the name and residence of the subscriber, and on the other side pictures of a Queen, Drone, and Worker, as shown here.

The Material entering into this celebrated knife is of the very best quality; the blades are hand-forged out of the very finest English razor-steel, and we warrant every blade. The bolsters are made of German silver, and will never rust or corrode. The rivets are hardened German silver wire; the linings are plate brass; the back springs of Sheffield spring-steel, and the finish of the handle as described above. It will last a last-time, with proper usage.

Why Own the Novelty Knife? In case a good knife is lost, the chances are the owner will never recover it; but if the "Novelty" is lost, having name and address of owner, the finder will return it; otherwise to try to destroy the name and address, would destroy the knife. If traveling, and you meet with a serious accident, and are so fortunate as to have one of the "Novelties," your POCKET-KNIFE will serve as an identifier; and in case of death, your relatives will at once be notified of the accident.

How appropriate this knife is for a present! What more lasting memento could a mother give to a son, a wife to a husband, a sister to a brother, or a lady to a gentleman, the knife having the name of the recipient on one side?

The accompanying cut gives a faint idea, but cannot fully convey an exact representation of this valuable knife, as the "Novelty" must be seen to be appreciated.

How to Get this Valuable Knife.—We send it postpaid for \$1.25, or give it as a Premium to the one sending us THREE NEW SUBSCRIBERS to the Bee Journal (with \$3.00). We will club the Novelty Knife and the Bee Journal for one year, both for \$1.00.

GEORGE W. YORK & CO.

St., Chicago, Ill.

Please allow about two weeks for your knife order to be filled.

Bee-Hives and Honey-Boxes

in car lots, wholesale or retail. Now is the time to get prices. We are the people who manufacture strictly first-class goods and sell them at prices that defy competition. Write us to-day.

AMERICAN

MASS. CT. AGRICULT. COLLEGE

BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., FEBRUARY 14, 1901.

FORTY-FIRST YEAR
No. 7.

WEEKLY

MR. GARIEL,
*A Parisian Apiarist, and one of the large bee-exhibitors
At the Exposition in 1889.*

PUBLISHED WEEKLY BY

GEORGE W. YORK & CO.

144 & 146 Erie St., Chicago, Ill.

*Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

IMPORTANT NOTICES:

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50c a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec'00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

Reformed Spelling.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "t" affects a preceding sound. Also some other changes are used.

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPERS' GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us two NEW SUBSCRIBERS to the Bee Journal (with \$2.00, and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street,

CHICAGO, ILL.

THE BEST WHITE

Extracted Honey

ALL IN 60-POUND TIN CANS.

ALFALFA
OR
BASSWOODALFALFA
HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD
HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

We have a good stock of the fine WHITE ALFALFA and WHITE BASSWOOD EXTRACTED HONEY that we can ship by return freight. Most bee-keepers must have sold all their last year's crop long before now, and will be ready to get more with which to supply their customers. All who have had any acquaintance with the above-named honeys know how good they are. Why not order at once, and keep your trade supplied?

Prices of Either Alfalfa or Basswood Honey:

For the purpose of selling again.

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are box. This is all

Absolutely Pure Bees' Honey,

The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:

I've just sampled the honey you sent, and it's prime. Thank you. I feel that I'm something of a heretic, to sell several thousand pounds of honey of my own production and then buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drink, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honeys of more market flavor, according to my taste.

McHenry Co., Ill.

C. C. MILLER.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

26 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 26 cents a pound—CASH—for best yellow, upon its receipt, or 28 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO.

* Editorial. *

Only One National Association.—Rev. A. B. Mettler, of Will Co., Ill., wrote us as follows, Feb. 1st:

1. Is the National Bee-Keepers' Association now in actual existence as the embodiment of the National Bee-Keepers' Union, the United States Bee-Keepers' Union, and the North American Bee-Keepers' Association?

2. And in consequence have these last three gone out of existence? Your quotation of Editor Root, on page 67, seems to imply this much.

3. And if so, when was it effected, where is its headquarters, and who are its officers?

If an amalgamation exists so that there is but one truly National Society instead of two or three or more, I think I would like to unite with it; for then something could be done efficiently, as all will pull together, and not pull somewhat together and somewhat apart, as must be the case where several societies are organized as "National" in the same interests.

4. What is the admission fee?

5. The American Bee Journal for Jan. 31st has arrived. I congratulate you upon removal of your office to a more convenient place. But say, do street cars run up Wells street to Erie street? If not, how near do they go?

6. I am 57 years old to-day, but have had only one birthday. If you can't guess how, I can I can tell you later on, if you wish to know.

A. B. METTLER.

ANSWERS.—1. The National Bee-Keepers' Association is now the only national organization of bee-keepers in existence. The National Bee-Keepers' Union was organized some 15 years ago for the special purpose of defense, never held a meeting, but did successful work until about a year ago, when it was amalgamated with the United States Bee-Keepers' Union, and the organization resulting called the National Bee-Keepers' Association. About five years ago the original national bee-keepers' organization, which was started over 30 years ago, changed its name to the North American Bee-Keepers' Association. Then at the Lincoln, Nebr., convention in 1898 the name was changed to the United States Bee-Keepers' Union. This left two bee-keepers' unions in the field, both being national in character, and were the two that united into one society about a year ago.

2. So, as before stated, there is just one—the National Bee-Keepers' Association—now in America.

3. Its headquarters are at Forest City, Iowa, where its general manager, Eugene Secor, resides. The full list of officers was published on the first editorial page of last week's Bee Journal.

4. The annual dues, or admission fee, is \$1.00.

5. Yes, the street cars run within one-half block of our new office, at 144 and 146 Erie street. The Wells street cars can be taken on what is known as the down-town loop, and for 5 cents you can come to our office from the center or main business part of Chicago. If one happens to get on a North Clark street car there will be no harm done, as this line crosses Erie street two and one-half blocks east of our office. But the least walking will be done by taking the Wells street cars.

6. We are usually not very good guessers, and so you will have to explain about your having had "only one birthday."

Management for Comb Honey.—Mr. L. Stachelhausen gives his method of producing comb honey as follows, in *Gleanings in Bee-Culture*:

As soon as the honey-flow commences, and the time arrives when we think it is best to set supers with sections on top of our hives, a hive is prepared with starters only. We bring it to the hive selected for the new manipulation. The old hive is removed from the bottom-board, and set aside to be handy for the following manipulation. The new hive is set on the old stand, and an empty five-body on top of it. In all these operations I use smoke, and handle the bees somewhat roughly to cause them to fill themselves with honey. One of the brood-combs, with bees and all, is put into the new hive, and then all the bees brushed from every frame into this hive. The most important thing in this operation is, that the bees fill themselves with honey. A little sprinkling with a solution of sugar in water can be used if the bees don't suck up the open honey.

The combs from which the bees are brushed into the new hive are assorted into different empty bodies near by—brood-combs, honey-combs, or empty ones separately. It is not necessary to look for the queen. She is brushed into the hive with the other bees.

At last we remove the empty body, lay a queen-excluding honey-board on top of the new hive; and a super with sections (containing preferably full sheets of foundation and some bait-combs) is set on top of this, and the hive is closed.

The next day the frame of brood is removed, and more super room given if needed.

Propolis.—As there is a possibility that propolis may yet become an article of commerce, the following from a report of a conversation reported in the *British Bee Journal* will be of interest:

"Propolis" was a remarkable product, medicinally used in liquid, not saline form as many supposed. It was considered to be a wonderful antiseptic, and had been employed successfully for wounds in South Africa. It was supposed to take the place of iodine, and some experiments showed that with about 3 percent emulsion of the liquid certain bacteria were killed off in two minutes, and other bacteria in three minutes. This "propolis" was stated to be very useful for foot and

mouth diseases. The mixture was also said to be very rich in oxygen and carbonic acid gas in a liquid form, and contained another alkaloid at present unknown. With regard to "propolis," Mr. Harris would like to know, seeing that its anti-septic properties had been proved, what the general opinion was as to its efficacy in the treatment of foul brood.

Mr. Reid, who had examined the bottle and smelt its contents, said that the liquid smelt of benzoline, and might be a gericide. Mr. Reid suggested that the germicidal properties probably existed, if at all, in the "unknown alkaloid."

Mr. Reid said that propolis, when taken out of the hive, always contained wax; generally it was nearly half wax, and wax invariably contained propolis, except when just secreted. It was possible to separate five or six different substances by the use of various solvents, but what those substances would do, or whether they were specific antiseptics, it was difficult to say. The bees themselves used propolis as their chief antiseptic. They would cover over objects of aversion (such as a dead mouse), which got by any means into their hive with wax and propolis—always the latter—and they would cover over the antiseptic provided for them with their own, which was better. A large percentage of propolis would be found in the dark cappings of cells containing foul brood.

Mr. Hanly-Harris, in concluding the discussion on "propolis," stated that the researches made by the inventor of the compound in question was sent up to the Medical Officer of Health for Prussia, and the latter gave his certificate that all the chemical and bacteriological properties thereof were as claimed.

A Suggestion for the National.—At the last meeting of the Chicago Bee-Keepers' Association the following was unanimously adopted:

WHEREAS, The National Bee-Keepers' Association has provided that local associations may join it in a body by payment of 50 cents for each local member; and,

WHEREAS, Abundant advertising is necessary for the success of any enterprise; therefore, be it

Resolved, That we, the Chicago Bee-Keepers' Association, do hereby request, and urge the National Bee-Keepers' Association to provide all local associations in America with printed matter setting forth the objects and aims of the National Association, so that the secretaries of such local associations may be able to put such printed matter into the hands of all bee-keepers in their territory and jurisdiction.

From the fact that there has been some call for information concerning the objects and work of the National Association, it would seem that there should be something printed for free distribution—that it furnish the desired information—so that it would not be so difficult for the officers of the local associations to get members.

It was at our suggestion that the provision was made in the constitution of the National Association to admit the members of the local associations at 50 cents each. We still

think that it was a good move, and believe that the provision would be taken advantage of if local bee-keepers understood about it, and especially if they were informed concerning the good work already done by the National, and also as to what it purposed to do, in the interest of every bee-keeper in America.

We trust that the board of directors of the National Association will act on the suggestion made by the Chicago Bee-Keepers' Association.

We also think that it would be a good thing if all the bee-papers would carry a standing notice, that every one desiring to learn about the work of the National Association could do so by sending to the general manager for literature that would explain the objects of the Association. It can not be expected that bee-keepers will unite with an organization until they know something about it. They must be led to see that it will pay them to do so before they will hand out their dollar-a-year dues. We believe that any legitimate organization will not suffer for the lack of funds if those who should be interested are shown that it is to their interest to support it, and that its objects are really wise, and for the advancement and defense of right principles and purposes.

Let the board of directors of the National Association prepare at once suitable literature as suggested, and begin its circulation as soon as possible thereafter, so that by the time of the next annual meeting its membership can be counted by the thousands instead of by the hundreds. We are ready to do our part in pushing the work of securing membership, thru the columns of the American Bee Journal, and have no doubt that the other bee-papers will do all they can along the same line. With united effort we believe there is no reason why the National Bee-Keepers' As-

sociation should not have a larger membership than any of the other agricultural organizations now in existence in this country. We believe the machinery of our Association is all right, and all that is needed is to work it. It needs to have its joints limbered up with the oil of enthusiasm, and the motive power of earnest effort applied to start it and keep it going.

Weekly Budget

MR. O. O. POPPLETON, of Dade Co., Fla., wrote us as follows, Jan. 29th:

"Bees are breeding nicely with an abundance in the hives. They would be gathering quite a little surplus honey now if the weather was only a little warmer.

"I had the misfortune, a couple of weeks ago, to drop the ax on my left forefinger, just above the knuckle joint, cutting it quite badly, and breaking the bone. The surgeon thinks the finger can be saved without its being stiff. It is doing fairly well now, but it will take a week for the bones to knit so the hand can be used. I don't find any special fun in being one-handed."

We regret to learn of Mr. Poppleton's accident, and trust that in time his finger may be all right again.

EDITOR WILL WARD MITCHELL, of the Progressive Bee-Keeper, after quoting the account we publish in the American Bee Journal of Jan. 10th, concerning our "fire-water" disaster, gives this appreciated paragraph:

We regret our brother publisher's misfortune, and hope his many patrons will pay up any back dues at once, as Bro. York has been

giving us his best efforts, and the "Old Reliable" is far ahead of what it ever was before. We know of nothing that would be more cheering to Bro. York than for delinquents to "pay up" and send in their renewals.

THE WISCONSIN CONVENTION was held at Madison last week as previously announced. It was a good meeting, and quite well attended, considering the poor honey season the past year.

The officers were all re-elected for the ensuing year, as follows: President, N. E. France; vice-president, Jacob Huffman; secretary, Miss Ada L. Pickard; and treasurer, Harry Lathrop.

Next week we will have more to say about the meeting and some of those who attended.

A DOZEN of the wealthiest capitalists in the country—men who wield absolute control over immense business enterprises—will tell the readers of the Saturday Evening Post (Feb. 16th) why they remain in the race which they have already won.

Each of them writes frankly whether he makes money for its own sake, for the sheer joy of working, or to gain the power with which vast capital invests itself. CRRITS PUBLISHING CO., Philadelphia, Pa.

MR. H. C. BINGER, one of our subscribers in Shiawassee Co., Mich., wrote us Jan. 28th as follows:

"Father past away Jan. 15th, at the age of 67. He was born in Mecklenburg, Germany; when 28 years of age he came to this country and settled at Rochester, N. Y., and there he was married to Miss Friederike Fischer, who, with five children, survive him. In faith he was a Lutheran, and was a kind and loving husband and father."

Contributed Articles.

No. 12.—Interesting Notes on European Travel.

BY C. P. DADANT.

BEFORE I leave Paris and its surroundings, I must tell you of two very pleasant trips I took in company with my daughter and our good friend Mr. Gariel, of whom I have often spoken. The first was a visit to a manufactory of bee-hives and implements located in a small town—Chartres—some 60 or 80 miles out of the capital. The flying express took us there in the morning and brought us back in the evening.

Of the factory itself I shall say nothing. It was a busy place, but those of our friends who are acquainted with American factories would find nothing of interest in anything I might depict, for their methods are not as practical as ours, and the work turned out is not to be compared, as I said in a former article, to anything that is made here. But I could perhaps give instances of the great economy practiced in the saving of material. This factory manufactures hives only as a secondary business, their main occupation being the making of railroad supplies of different kinds. Well, I saw large piles of old railroad ties (which would be sold here for fire-wood cut up into small pieces, and a good portion of the material set aside for the manufacture of a number of small articles which could very readily be cut out of this refuse. It takes more time, it is true, to pick out the sound wood, but the Europeans can not use our axiom, "Time is money," to as much of a purpose as we can, for altho with them time is also money, there

are many things that are more valuable than man's time over there.

The cheapness of labor is very certainly responsible for some very queer notions. For instance, a certain manufacturer seriously asserted to me that it was cheaper for them to have the lumber planed by hand than by steam. "It costs so little," he said, "and the work of a smoothing-plane is always neater than that of a steam planer. And in the use of second-hand lumber we need not be so afraid of the nails which would very soon spoil the steam knives." I tried to discuss the matter but it was of no use, and it is also evident that many working men do all they can to discourage the employment of time-saving devices which they consider as their enemies.

We were splendidly treated by the manager, who is evidently an able man and who asked me a number of questions about America and its factories. He was well acquainted with a gentleman who was in the employ of the railroad company as civil engineer, and who had been sent to America to buy a number of locomotives, and whom I happened to meet on our trip across the ocean, so we had quite a talk about the great steps that America is making in her trade with the world at large, and the numerous exports which are just beginning to bring the New World into competition with the Old.

We partook of a very nice dinner in his home, close by the factory, and employed the afternoon hours previous to the departure of the train, in walking about the old city, its walls, and the little stream which runs at their foot and in which the housekeepers were busy washing their linen. It was very picturesque. On another day we went with Mr. Gariel again, to visit an old and experienced bee-keeper—Mr. Delepine—cure of Menlan, within an hour's ride of Paris. Mr. Delepine is not only a practical apiarist, but is also a writer on bee-culture. He writes regularly for the weekly journal entitled, "La Gazette du Village," which might very properly be called the "Farm Journal" of

France, for it is a neat, newsy, and practical farmer's paper, full of interesting information. The trip to Meulan reminded me very much of "L'Abbe Constantin," by Halévy. I have no doubt many of the readers of the American Bee Journal have read that little book, for it has been translated into English and has become a classic.

Well, the kindly, good-humored cure, his old servant, his little garden, the little church, the little village, and even the big castle at a short distance on the opposite side of the road—all these things look familiar altho seen for the first time. We found ourselves there with Mr. Giraud, whom I have mentioned as so successfully putting in practice the Poolittle method of queen-rearing, and with an old gentleman—a count who kept bees for pleasure—and we had quite a talk on America and our American celebrities in bees. If I am not mistaken, two of the persons present could read English and had read *Gleanings* and a few copies of the American Bee Journal and "A B C of Bee Culture." Why it is that so few of the French can speak or read English is more than I can comprehend, but they seem to think it much more astonishing that not all foreigners can speak French. They seem to think that the French language ought to be an indispensable part of any good education.

Entrance Gate to the City of Chartres, France.

I think this makes the French more exclusive than other nations. Then their literature seems to encourage them in their ideas of exclusiveness, for it is certainly very wealthy in able works and books which have become classics, and more translations seem to be made from the French than from any other tongue.

We left Meulan after a very pleasant chat and a visit to the fine park of the castle across the way.

What a difference between European and American landscapes! I vainly tried to imagine myself in America, at different times. There was always something in sight to dispel the illusion. The village houses huddled together as in a nest; the white walls and red tile roofs; the magnificent country roads with their avenues of trees on each side; the little patches of land looking for all the world like so many handkerchiefs lying side by side in the sun; the smooth little streams of water, running quietly even to the edge of their grassy shores, and shaded with willows and poplars along their windings; the herded cattle, the two-wheel carts and their heavy loads, even the country buggies, showed me that this was another world. O, those buggies! What a look of contempt our farmer boys would give them! They are not buggies, but carts very gaudily painted, but so heavy! Wheels five feet high, shafts made of 4x4 timbers, springs to suit, harness ditto, and a big Percheron for a trotter. I nowhere saw one of our American spider-web buggies. I have no doubt that there are some in Paris, yet they must be scarce. There are plenty of fine carriages, and expensive equipages, but you can not, on the public roads, meet a light top-buggy at every turn. Their lightest buggies are made to last, and are heavy in every particular. This seems an absurdity, for such vehicles as we use here, on our abominable American roads, would be a delight over there. The harness also is heavy. It seems as if they were afraid the horse would break it, and there is enough leather in the lightest harness to make three such harnesses as our buggy-horses wear.

A Few Words of Comfort for "Old Grimes."

BY "THE MILLER O' THE DEE."

"Old Grimes is dead: that good old man,
We ne'er shall see him more."

SO the old ballad has it, but it now seems that he was not dead, but sleeping—aye, sleeping long years, like Rip Van Winkle, and he has only just awakened. (See page 20.) Poor, sleepy Old Grimes, who would have thought that one of your kindly, genial, helpful nature would have put even the semblance of discouragement in the way of any one, even of one so lost to all rectitude as to try to invent new devices in beddom?

You kindly old men did, indeed, beat paths for the rest to follow, even as our forefathers blazed the rude trail to the frontier; but who now would care to stumble over the logs and stones of such paths, when the same end may quickly be reached by automobile? Those old paths are full of pretty places, romantic spots and picturesque corners where wild flowers lend their sweetness and the drowsy hum of the bumble-bee invites one to tarry and repose. We all love those places to rest in, and the companionship of the placid plodder of these byways, but they are not for present-day commerce, nor can we travel over them in up-to-date vehicles.

The feeling which caused you, dear Old Grimes, to complain, is but a sound and safe conservatism allowed to run riot. But then, we must needs be charitable to you, for your article clearly shows that you have in mind only the devices shown in ancient times, and which indeed needed bees from fairy-land to construct combs for use in them.

What a nightmare your dreams have been, for now, just half awake, you mutter of slicing-machines, of hills and hollows, of long adjusting, of high prices, of revolutions, of systems, of new outfits, and other fits and misfits. Come, come, Father Grimes, take a cold plunge, shake thyself and awake, for thou art still more than half asleep. Thy ideas and reasoning bespeak of cobwebs in thy brain, and are not worthy the 20th century.

'Tis far from the thoughts of these troublesome inventive fellows to put obstacles in the paths of you old fellows—no, no! they would much rather help you into the broad, smooth highway, and when you longingly turn from its rush and bustle into the sweet, tho' sleepy, quiet of the old paths, they would furnish you with a rugged cane to help your tottering steps over its stones and hummocks.

I know a little about some of these new-fangled machines, and to save you from further worry let me whisper to you that an uncapper costing \$20, and that has to be "adjusted," is as far from the realized dreams of those ingenious fellows as you can imagine. No, they do not cost nearly so much, and their capacious maw will take all the combs as they come, and deliver them to you neatly *uncapped*, and at the rate of 20 a minute, if your trembling hands can feed them in so fast.

Dear Old Grimes, we all love you for your kindly charities, and for that quaint figure in its "old black coat, all buttoned down before," even tho' the color is now rather gray from the dust of many years.

So let us help you as you tread

That path of olden times;

All undisturbed, rest in thy rut

For evermore, Old Grimes.

Getting Bees to Swarm - Requeening, Etc.

BY EDWIN BEVINS.

LAST spring I discovered a means of getting bees to swarm at almost any time when swarms are desirable.

One of my colonies was wintered in two sections of a sectional 8-frame hive, sections 7 & 8 inches deep. Early in May the colony got so strong that in order to prevent swarming I placed another section under, filled with drawn combs. When supering time came, I raised the upper story and put a queen-excluder under them, then shook the bees from every frame down in front of the entrance. I felt sure the queen was below, and expected the brood in the upper story to mature and make room for honey to be stored there by the time there would be much to store.

No further attention was paid to these bees for several days until one day a neighbor expressed a desire to look over the apiary. In showing him around I happened to raise the cover of the hive and lift some of the combs. To my surprise I found brood in all stages of development, and every

comb full. On one of the combs I found the queen and put her below. The next day but one, some one coming into dinner said the bees were swarming. I said, "What are the bees swarming for? I don't believe there is a queen-cell in the yard." But noticing that the air was full of flying bees I went out to see what hive they were coming from. It was from the hive in which I had put the queen below the day but one before. The cause of the swarming was not hard to understand. The bees clustered in two places, and, suspecting that each cluster had a queen, I hived them in two hives. One cluster was large, and I hived it on a Langstroth frame; the other I put into an 8-frame dovetailed hive. Each cluster had a queen.

After hiving them I went to see what was going on in their old home. I found a queen in possession there, and quite a number of cells, from which the queens had issued. I reduced the old hive to two sections, and left it that way for the balance of the season. When packed for winter it was so heavy with honey that I did not care to lift it. The two swarms stored their winter's supply, notwithstanding the season had been an unusually poor one for honey. These were all the swarms I had the past season.

Another colony wintered in two 10-frame dovetailed hive-bodies on 17 frames, had a queen nearly or quite as prolific as the one just mentioned. The last of April the two stories were so full of bees that I put another story under, containing 9 frames. About the first of June the three stories seemed to be full of bees. An examination showed that there was no brood in the lower story, but the one above, which also contained 9 frames, was practically full of brood, and the upper one seemed to be about half filled. As the upper story contained much honey I removed the middle story to another stand, knowing that most of the bees would go back to the old location. I did not see this colony again for several days, but when I did I found a queen on the first comb I raised. Another mature queen was found on another comb. Then I formed a nucleus and gave it to one of the queens. The queen left in the hive proved to be an uncommonly good one, even if it was reared in a manner which queen-breeders generally condemn.

SELECTING A HOME BEFORE SWARMING.

Do bees intending to swarm hunt up a place to go before the swarming takes place? I guess they do sometimes. One season I noticed bees in great numbers entering a hive which stood on another hive at the upper side of the bee-yard. The hive had some empty combs in it. I lookt about to see where the bees were coming from, and found them pouring out of a hive at the lower end of the yard and taking a bee-line for the hive at the upper end of the yard a distance of about 4 or 5 rods.

REQUEENING COLONIES IN THE FALL—MAILING QUEENS.

I unqueened and requeened one-fourth of the apiary last fall. Most of the work was done in October, but it was not finished until some time in November. One reason why I like to do this work so late in the season is because in almost every instance I found the bees too deep, and as they have nothing from which to start queen-cells I don't have to be very particular about the time of introducing. In two instances there was a little brood, but as the queens were delayed I had a chance to destroy queen-cells.

The queens were from different parts of the country, and from breeders of good repute, and I have reason to believe they were all safely introduced.

I shall continue to order queens to be sent thru the mails, as I do not believe that many are injured in transit. Four queens ordered last fall were received dead. One of these was delayed in the mails at a time when the weather was hot. Two others had received such a shock that the cages were split from end to end, and had been tied up with string. The other cage had the queen and the bees all dead in it, doubtless caused by the same shock which split the cages of the other queens, as they came in the same mail.

When I received queens with pasteboard covering the entrance to the candy it was promptly torn off, and I had no queens killed in consequence of being released too soon.

I do not think that Mr. Fred Tyler need to worry about his bees getting too warm packed as he describes on page 79 (1900).
Decatur Co., Iowa, Jan. 7.

The Premiums offered this week are well worth working for. Look at them.

Convention Proceedings.

Report of the Proceedings of the 31st Annual Convention of the National Bee-Keepers' Association, held at Chicago, Ill., Aug. 28, 29 and 30, 1900.

BY DR. A. B. MASON, SEC.

Continued from page 86.

MELTING CANDIED EXTRACTED HONEY.

QUES.—What is the lowest temperature at which candied honey will melt?

Mr. Aikin—*I think* about 100 degrees, or a little better, but you must continue the heat for a long time; about 110 to 120 degrees will melt it in a few hours. The highest degree that I wish to subject my honey to is about 160 or 170 degrees; beyond that it begins to spoil the flavor. An additional question on the same sheet is: "What is the highest temperature it will bear without injury?" About 160 or 170 degrees is high enough. I would rather melt at 140 or 150, keeping it a longer time at that degree than to use the higher temperature.

APIS DORSATA AND THE NATIONAL ASSOCIATION.

QUES.—What is the attitude of this Association in regard to importing *Apis dorsata*, the big bee of India?

Mr. Aikin—If I am to answer that, I believe it is opposed. I don't know.

Dr. Mason—Opposed until we know more about it.

QUES.—Have any steps to procure or test these bees been taken?

ANS.—Yes, there have.

Mr. Benton—The attitude of this society did not seem to be that at the Buffalo convention, and I was wondering whether it had changed, considering your answer.

Mr. Aikin—I judged from the sentiment as expressed thru the bee-papers of late—I said I thought, I do not know. I suppose the only way we could come at it would be by taking the temperature of the people here now. Are you thru with this subject?

REQUEENING AN APIARY.

QUES.—What time of the year is best to requeen an apiary, all things considered?

Mr. Aikin—Dr. Mason, answer that.

Dr. Mason—Why, I really don't know. I prefer to do it during the honey-flow, myself, and by natural methods. I don't use the artificial methods.

A Member—Early or late?

Dr. Mason—Late.

A Member—How late?

Dr. Mason—For convenience, that is all. I don't believe it makes any difference as regards their good qualities which stage, early or late.

A Member—You would say just after the honey-flow?

Dr. Mason—Just as it is closing up, before it closes. They must have the vim and energy they have when the honey-flow is on.

A Member—How often would you requeen?

Dr. Mason—Once in two years.

MATING IN CONFINEMENT—SPREADING BROOD.

QUES.—Can the queen mate with the drone if the queen and drones are confined in a tent or other inclosure, say 200x100 feet?

Dr. Mason—No.

QUES.—Is it any benefit to spread brood in early spring?

Mr. Aikin—Prof. Gillette, please answer that.

Prof. Gillette—Let some one with more experience answer that.

Mr. Poppleton—Yes.

A Member—Sometimes it is, and sometimes it is not, depending principally upon the man or woman who manages it. If you know how, it is all right; if you don't know how, go slow.

KEEPING EXTRACTED HONEY.

QUES.—How long will extracted honey keep?

Dr. Mason—I don't know; it has never been tried.

Mr. Aikin—I have some that is getting to be pretty nearly half as old as I am.

Mr. Coggs—shall I have some 30 years old.

Mr. Aikin—Is it good?

Mr. Coggs—shall I haven't opened the package.

Dr. Mason—I have some that is 15 years old that stands open—good yet.

TO PREVENT GRANULATION AFTER FEEDING.

QUES.—For feeding what would you put with sugar syrup to prevent granulation, and what proportions?

Mr. Aikin—Some use honey; I never had any experience. I can't answer it.

Mr. Hutchinson—Honey is all right for that; about one-quarter honey is all right.

Mr. Benton—One-fifth will do.

Mrs. Acklin—Percolate the syrup and you don't have to put any honey in.

WHAT TO DO WITH FERMENTING HONEY.

QUES.—What can you do with frames of honey that is fermenting?

A Member—Extract it and sell it.

Mr. Aikin—Feed it to the bees, or make vinegar of it.

A Member—Will it do to feed to the bees?

Mr. Aikin—I wouldn't feed it to the bees any time except when they could fly freely, and I have some doubt about it then; I said that because somebody else was recommending feeding.

SPENDING THE FUNDS OF THE ASSOCIATION.

QUES.—How large a percent of the funds of this Association should be used in the prosecution of adulterators of honey?

Mr. Abbott—It depends upon circumstances. We would have to decide that when the case came up.

QUES.—Would this Association deem it better to have a good, fat sum in the treasury, or should the money be very nearly exhausted each year in the various lines of work for which the Association was organized?

Mr. York—I think it ought to spend its money in the interest of its members. If more is needed at any time for legitimate purposes, call for more from the members.

Dr. Mason—Money is no good when it lies idle.

AN ASSOCIATION BRAND FOR HONEY.

QUES.—Should this Association prepare an association brand as a guarantee of purity of honey, which it can supply to certain applicants upon the unanimous approval of the board of directors?

Mr. Aikin—For my part I would answer that in the negative, until this Association becomes more properly a business concern.

BEES POISONED FROM UNTIMELY SPRAYING.

QUES.—Is it a fact that bees are poisoned and brood killed when fruit-trees are sprayed while the trees are in bloom, and the bees are visiting them?

Mr. Aikin—Colorado people say yes.

Mr. Benton—Other people say yes.

Mr. Aikin—A person in my county was convicted and fined for spraying his trees while in bloom, and thereby killing his neighbor's bees.

Mr. Prisk—I think in referring to that the other day, when I spoke about the sulphuric acid killing the bees where the smelters were, somebody made a reply that they thought that smelters did not kill the bees. In our town we have large smelting works, and in our yard, and for blocks around, everything is killed. I have known arsenic to collect to a large amount in a few hours and to kill the shrubbery around there, and we thought that probably it fell to such an amount on the bloom that that killed the bees. We noticed the bees always came home as if they were tired out, and did not leave their hives.

ARRANGEMENT OF BEES WHEN SUPERING.

QUES.—When putting on the supers for comb honey should the natural arrangement of the brood be interfered with?

Mr. Hutchinson—I should say no.

Mr. Hatch—I wrote that question myself, because I tried an experiment this summer that convinced me it is profitable to interfere with it, and judging from this one experiment I should say decidedly it should be. My experiment was to move all the eggs and unsealed larvæ to the outside of the hive, to fill the hive full of brood, and put all the bees and unsealed larvæ clear on the outside. The re-

sult was I got a big yield of comb honey, and the outsides were filled up first. Whether it would work always that way or not I don't know. Of course, I only tried it one season; but I think it is a subject worthy of further experimentation.

Mr. Abbott—Mr. Hatch is appointed to experiment next season.

Mr. Hatch—I undoubtedly will.

THE HONEY CROP AND HANDLING.

QUES.—What percentage of the national honey crop is represented by the membership of this Association?

Dr. Mason—I don't know, and I don't believe anybody else does.

QUES.—Would it be practicable for the Association to handle the crop of 1901 for its members?

Mr. Abbott—No, nor at any other time.

Dr. Mason—I don't believe that; that is, the last part of Mr. Abbott's statement. I'm a firm believer in co-operation.

QUES.—If impossible, by what obstacles is the possibility precluded?

Dr. Mason—That matter is like all other matters, it has to develop itself slowly. I believe that this Association will some day get in position to handle the honey of its members; can't be done yet; it is going to take time.

A Member—Is it not possible for this Association to go into a joint-stock corporation and handle all their honey, buying all the honey in the country and handle it for the benefit of the members? I think it is possible. I don't see anything to prevent it, if all the honey could come in here and be graded by disinterested parties.

Dr. Mason—Are you asking me that question?

A Member—Yes, sir.

Dr. Mason—I think I can answer that question. I don't believe there are a dozen members of this Association that would be willing to ship their honey and wait for their pay; it takes money to run any business. Will you put the money in?

A Member—The honey will bring the money.

Dr. Mason—It has to be handled, and all bills paid; it takes money to run any business; this has to be developed.

A Member—Why can't the bee-keepers, furnish that money pro rata?

Dr. Mason—Well, I don't know why they can't; but will they?

Mr. Aikin—I would like to say for the information of all interested, that some of us in Colorado have been thrashing that ground over and over again in the last four or five years, until we have got down to a working basis; I am going to tell you a little of it to-night.

QUES.—Should this Association undertake to find a market for its members?

Dr. Mason—It is answered in what has already been said—not at present.

WIDE AND DEEP HIVE-ENTRANCES.

QUES.—Is it an advantage during hot weather to use wide and deep entrances in the production of comb or extracted honey? If so, is there any danger of going to an extreme?

Mr. Wood—I use both large and small entrances, and I see no difference. I use chaff cushions on top of my hives the year round, and I find them better than none at all.

COMB FOUNDATION—COMB HONEY.

QUES.—Is it more profitable to use thin foundation than extra-thin in supers? and, if so, why?

Mr. Aikin—I believe extra-thin would be my answer, and the way of it as put before us this afternoon by Prof. Gillette.

QUES.—Is comb honey in drone-cells as pretty and as white as that in worker-cells?

Mr. Aikin—It depends upon who is looking at it: ordinarily it doesn't appear as white looking.

REMOVING SUPERS HONEY OOOZING OUT.

QUES.—When should the supers be taken off?

Mr. Aikin—When they are full, and the unfilled ones as soon as the honey-flow stops.

Mr. Holdren—What is the cause of honey oozing out of the cells after it is filled all up in that way?

Mr. Aikin—I don't know why it is fermentation, perhaps.

Mr. Holdren—What causes the fermentation?

Mr. Aikin—I wouldn't know how to answer that, unless it is too much water—unripe honey.

Mr. Holdren—I had my honey in a very light place upstairs, and some of it oozed out in that way.

Mr. Abbott—Bees frequently gather honey that will ferment, especially in localities where there is basswood. Sometimes bees gather honey during damp weather that they can't fully ripen, and I have had large quantities of it ferment in that way, and just as soon as it becomes ripened it will granulate. In some seasons I was troubled badly with it in Missouri, and other seasons I would not have any of it. I think it is owing to the dampness of the honey when gathered, the bees not being able to ripen it fully.

(Continued next week.)

Report of the Utah Bee-Keepers' Convention.

BY A. F. STEVENSON.

The Utah State Bee Keepers' Association held its annual convention in Salt Lake City, Oct. 6, 1900.

The meeting was called to order by Pres. Lovesy, and after the reports from committees were read he gave some general reports from different parts of the State. The meeting was then thrown open for discussion of topics of general interest to the fraternity.

GENERAL REPORTS FROM MEMBERS.

Andrew Nelson, of Emery Co., had harvested a very good crop of honey during the past season, but he said that something was wrong with some of the bees, possibly foul brood, and, if so, he would like to know of some way to get rid of it. The condition of the brood was described, a discussion among some of the experienced bee-keepers followed, and they decided that it must be pickled brood. Some time was taken in discussing cures for foul brood. The bees should be looked at early in the spring, and if any brood is found with the backward presentation it is sure to turn out to be foul or pickled brood, and when such conditions are in evidence the bees should be transferred onto foundation in clean hives; but if they are left until rotten it is best to destroy both bees and brood.

James Jackson, bee-inspector of San Pete Co., said there was some foul brood in Mt. Pleasant and other parts of the county, and it seemed to be almost impossible to get rid of it entirely.

Mr. Lovesy found in 10 years of experience that it was always best to transfer the bees just as soon as the backward presentation was noticed, even if at a time when the bees would have to be fed, as even at this early stage the disease will have been in the hive two weeks or more, and the young larvae in their agony have turned over, leaving the head in the bottom of the cell, which makes it impossible for them to hatch out.

Joshua Terry, of Salt Lake Co., reported a poor crop, and the situation very discouraging. His bees had dwindled from 90 colonies to 15, the principal cause being smelter-smoke. Mr. Cornwall of the same county was also a heavy loser from the same cause. He moved some of his colonies several miles from the smelter-smoke, and they continued to die for a week, after which they began to do better, while all of those left at home soon died. A resolution was adopted authorizing the Association to use all possible legal means to get rid of the nuisance.

L. Yeale, of Tooele Co., reported a fairly good crop, tho not as heavy as in former years. Several reported a light crop in the southern part of Davis County, while in some of the northern portions the flow was good. They reported some cases of foul brood, and no inspector to attend to it, tho they expected to have one soon.

Mr. Nelson gave his experience in packing for winter with burlap, straw, chaff, etc. Mr. Stevenson was also successful in packing with straw and chaff mixt, raising the covers about 1/2 of an inch for ventilation.

Geo. Hone reported that Utah honey had produced only about half the amount of honey secured in other years. In speaking of winter packing he thought that two or three thicknesses of burlap over the brood-frames, with a super on top, was a good way.

Frederick Schach, of Salt Lake Co., reported a poor crop; he thought packing for winter was all right, but the bees must have sufficient ventilation or they would sweat, get weak and damp, and then die.

A general discussion followed in regard to exhibiting at fairs, and also in regard to the purchasing of bee-supplies and disposing of the products of the bee. A vote of thanks was tendered the officers of the Association

for their efforts in supplying members with information as to honey prices, as this had a tendency to keep up prices, and thus benefit the bee-keepers and the industry.

Several from Weber County had a full average crop, some of the bee-keepers there averaging more than twice the amount of both comb and extracted that some bee-keepers in Salt Lake and other counties secured. Mr. Reese secured over a car-load of No. 1 extracted honey. As prices have been above the average this season he is one of the lucky ones.

THE PRESIDENT'S ANNUAL ADDRESS.

The many reports we have received taken as a whole are not very flattering or encouraging. While we have received some flattering reports of a good honey-flow and a good crop for bee-keepers in the southeast and south central parts of the State, further south they have not been as good; and while in the northern parts of the State the reports have been fairly good in some localities, in the north central parts, owing to drouth and grasshoppers, the reports have mostly been from 1/4 to 2/3 of a crop, the average in some instances being as low as 30 to 35 pounds. One of the remarkable features of the season has been that while there was very little honey in some localities, in favorable localities a few miles distant there would be a good honey-flow. These favored spots were generally in or near the base of the mountains, where there was plenty of irrigation, and few or no grasshoppers. To many of our bee-keepers the last year of the century will prove an exasperating failure. Altho we had a beautiful spring, the dry, hot June—the hottest ever known in the State—dried up the bloom and irrigation; and as misfortunes seldom come single-handed, then came the grasshoppers in such numbers in some localities that they ate everything green. When things began to look discouraging, both for the past season and the next, our friends—the gulls—came by the tens of thousands and devoured the grasshoppers by the wholesale. So most of the bees have plenty of honey for winter, with some surplus, and the chances are more favorable for another season, on account of the work of the gulls.

The Association has been of material benefit to many of our bee-keepers, in keeping them posted as to the value of bee-products; we have been duly assisted in this matter by Mr. F. L. Thompson, of Colorado, and the bee-keepers that have been governed by the advice given, have saved money by it. This union of interest is certainly a step in the right direction, and we hope it will be extended to the purchasing of supplies next season. Too much credit can not be given Mr. Thompson and others in their unselfish interest in this matter.

The smelter-smoke is still a matter of much concern to many of our bee-keepers. This matter has been thoroly tested in Salt Lake County the past season, by placing colonies of bees in different directions and distances from the smelters, and we find that all bees placed within five miles of the smelters in the direction the wind usually blows, die off in from three to five months, while many 8 or 9 miles away die during the year. But bees placed within two or three miles of the smelters in the direction that the wind does not blow, do not seem to be affected at all. It has also been proven that much stock and vegetable matter have been destroyed by this smelter-smoke. Arsenic, or something of that nature, settles from the smoke on the trees and plants, causing a destruction of life, as stated. In the light of these facts some method should be adopted to have this poisonous smoke consumed, or otherwise prevented from being sown broadcast as it now is. E. S. LOVESY.

Mr. Ulrich Bryner, of Carbon Co., said that his bees were in good condition, and had done better this season than ever before. He secured 200 60-pound cans of extracted honey from 85 colonies.

Thos. Neilson, of Sevier Co., reported that the season's crop was considerably below the average.

Mr. Balliston, of Juab Co., reported a fairly good honey-flow in that county, but not as heavy as it had been in some years.

J. A. Smith, of Wasatch Co., reported a fairly good crop for his county, altho they had harvested larger crops in other years. Wasatch is one of the counties in which there is a good flow of first-class honey in ordinary seasons. Mr. Smith heartily endorses the efforts of the Association in trying to keep up the prices of bee-products, thereby aiding the bee-keepers in building up the industry.

Uintah County reported the best honey-flow of the season, and is the banner county of the State. A score or

more of the principal bee-keepers of the county harvested 318,400 pounds, and altogether the county has produced about 500,000 pounds the past season.

After a discussion on how to increase honey-producing plants the meeting adjourned, subject to the call of the president.

A. F. STEVENSON, *Reporter.*

Salt Lake Co., Utah, Oct. 27, 1900.

"The President's Message" to the Ontario Co., (N. Y.) Convention.

BY W. F. MARKS.

ANOTHER year has past since last we met, and left us, as honey-producers, richer only in experience, the past season being the poorest season for honey ever known in our county if not through a large portion of the continent. But altho the past season has been the poorest of several poor seasons with us in the production of honey; altho our bees have failed to gather us any surplus, we can feel that our labor has not been in vain, for our pets have never yet failed to fulfil faithfully the prime purpose for which they were created, whereby all are benefitted.

Miss Morley says, "The Vedic poets sang of honey and the dawn at the same moment, and all the succeeding generations of India have chanted honey and its maker into their mythologies, their religions and their loves."

"The philosophers of Greece esteemed the bee. And without honey and the bee the poets of Hellas would have lacked expressions of sweetness that all succeeding ages have seized upon as consummate."

"The Latin writers studied the bee not only for its usefulness as a honey-maker, but because of its unique character for industry, for its skill as a builder, and for its wonderful sagacity in its social organization."

"Modern writers are principally concerned with the structure and habits of the bee as revealed by modern science, and particularly with the part played by it as a fertilizer of the fruits and flowers."

"To fertilize the flowers has always been the office of the bee, as we can see now that the processes of nature are understood."

"At the present time sugar has superseded honey as an article of every-day use. Honey has lost most of its importance in the family life, but not so the bee, for we know that it does inestimable service in perfecting the fruits of the earth, and that without it our orchards would be lean and our gardens barren."

Notwithstanding the acknowledged importance and necessity of the bee as a factor in agriculture and the arts, we are to this day called upon to fight for its very existence.

At the last session of the legislature the opposition, I have reason to believe, started in to repeal our excellent spraying law; but, finding that its friends were awake and ready for the fray, they contented themselves by asking for an amendment to the law to allow experiments by the directors of the experimental stations at Ithaca and Geneva. Originally the amendment had the words, "whenever and wherever desired in this State;" we had these words stricken out. As finally amended, believing that the proposed experiments would sustain the bee and strengthen the law, it was allowed to pass without further opposition. These experiments have not yet been published. Perhaps it will not be proper for me to anticipate the result of these experiments, but I have reason to believe, from what I can learn, that we have nothing to fear from them, and that they will only emphasize the fact that it is not only unnecessary but absolutely injurious to spray during bloom. I learn that in one of the experiments of spraying in bloom, the yield of fruit was just one-half of what it was where the spraying was done just before the blossoms opened. That certainly is not "making two blades of grass grow where one grew before," but the very reverse. The result in all the experiments may not have been as emphatic as this one; it could hardly be expected.

Plato in his laws written 370, B. C., makes it a crime to poison bees. His law translated reads as follows: "He who employs poison to do an injury, not fatal, to a man himself, or to his servants, or any injury, whether fatal or not, to his cattle or his bees, if he be a physician, and be convicted of poisoning, shall be punished with death; or if he be a private person the court shall determine what he is to pay or suffer." Thus it will be seen that we have a precedent that was established nearly 2300 years ago.

"The mills of the gods grind slowly." It is thus with the Apis dorsata enterprise that you have so persistently advocated. I can assure you, however, that this undertaking is certainly making progress; one thing is certain, Providence is on our side, and, altho he has not yet succeeded in importing these bees, he has given us their native land, and dorsata is getting accustomed to the star-spangled banner. I believe they are willing subjects, as there are no reports of their having joined the insurgents! I trust the opposition will not start such a report, and that they have stung, perhaps killed, one-half, more or less, of our little army, and driven the balance into the China Sea! Yet such a story would be just as reasonable as many that have been circulated in relation to this bee.

Perhaps the subject of marketing honey is quite out of place this season, owing to the fact that we have none to market; but if we should be fortunate enough to secure a crop again we should endeavor to maintain prices now that they have advanced.

The National Association has recently issued a pamphlet, larger and more complete but similar to the one we published over a year and one-half ago. Such pamphlets are very useful. I wish that all this matter—showing the relation of bees to horticulture—that has been published by the Department of Agriculture, the various experimental stations, and other recognized authorities, with the experiments now being made at Ithaca and Geneva, in relation to spraying in bloom, with accompanying illustrations, could be published in one bulletin. This matter of the bee and its importance to agriculture can not be proclaimed too much—the people should be made to realize their obligations to the honey-bee.

I will briefly call your attention to Article 3, Section 2, of the Constitution of the National Bee-Keepers' Association, which read as follows:

"Whenever a local bee-keepers' association shall decide to unite with this Association as a body, it will be received upon payment by the local secretary of 50 cents per member per annum, provided that the local association's membership dues are at least \$1.00."

This is carrying out the ideas embodied in our State organization, and, if adopted by our association, would admit us to membership not only in our county and State associations, but in the National also, and all for the small price of \$1.00 per annum. I would recommend that our constitution be amended so as to enable us to take advantage of this provision of the National Bee-Keepers' Association.

In my several previous messages, with which you have been afflicted, I have by turns coaxed and scolded the beekeepers of the county for carelessness, or indifference, shown by them for not taking greater interest in these meetings. The fact that you have realized but little from your bees for a couple of seasons should not deter you from aiding and strengthening our organization. The more interest you take in it the more pleasure and benefit you will derive from it. Do not wait for the secretary to urge you. Each of you has some subject—perhaps several—relating to our pursuit, upon which you have well-founded ideas. Notify the secretary, and let him put you on the program. Take pride in our organization and pride in our pursuit; it may not be the largest industry, but it is just as honorable as any. Bees are said "to have been the heralds of civilization, steadily preceding it as it advanced." That they have always been held in high esteem by man can not be questioned, as they are mentioned as far back as history extends. They figured in the symbolical history of Egypt nearly 4,000 years B. C., showing with what esteem they were held nearly 6,000 years ago. Let me repeat, take pride and interest in your pursuit, that the bee may ever remain where history and science place it—the most interesting and important member of the animal kingdom.

The Chicago Convention Picture is a fine one. It is nearly 8x10 inches in size, mounted on heavy cardboard 10x12 inches. It is, we believe, the largest group of beekeepers ever taken in one picture. It is sent, postpaid, for 75 cents; or we can send the American Bee Journal one year and the picture—both for \$1.00. It would be a nice picture to frame. We have not counted them, but think there are nearly 200 bee-keepers shown.

The American Fruit and Vegetable Journal is just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both for \$1.10.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Boiling Foul-Broody Hives, Newly-Hived Swarm Leaving.

1. If I boil hives and frames that have been taken from foul-broody bees, will it kill the germ? and will they be safe to put bees in again?
2. Can one tell whether the disease is foul brood or pickled brood when it is found in an early stage? If so, how?
3. Last season in swarming-time it was quite warm, and in hiving bees they would leave the hives soon after being put in. A remedy was tried of cooling the hive with cold water, and after letting it drain put the bees in, but they would leave them. Mint was tried, and had but little success. The hives were new, and had foundation on each frame. Please suggest a remedy. What do you think was the reason of their deserting? UTAH.

ANSWERS.—1. Yes, and some good authorities say it is safe to use a hive of the kind without boiling.

2. You can hardly be certain till some advance has been made. Look up the subject in the last volume of American Bee Journal.

3. When a swarm is hived and leaves the hive, in a large proportion of cases it is because the hive is too warm. Sometimes wetting with cold water will help, but if the hive stands in the sun it may still be hot in spite of the wetting, especially if the hive is close. Let the hive be raised from the bottom-board, and perhaps the cover open a little for a day or two. Some give to a swarm a frame of brood. Bees are not likely to desert this.

Queen and Swarming Questions.

1. What percentage of queens reared by a strong colony, and then 3 days before hatching being given to nuclei, would swarm the same year?
2. What percentage of virgin queens would swarm, if allowed to hatch before being introduced to nuclei?
3. Would it be better to let each nucleus rear its own queen, providing each had 4 or 5 frames of sealed brood with one containing some eggs, and all being well covered with bees?
4. What would be the best method to increase from 30 to 55 colonies and keep swarming down?
5. Would it make any difference in the harvest if all old queens were replaced by virgin queens 45 days before the flow? or would it be better to give them fertile queens of this year's rearing? and what difference would it make in swarming? SUBURBANITE.

ANSWERS.—1. I don't know. If you will tell me what will be done with the queens afterward, I may be able to tell something about it. Your question is such as to suggest that you suppose a queen reared in a strong colony and given to a nucleus three days before hatching will give results as to swarming quite different from one that has not been given to a nucleus. I doubt that. It is not so much what has been done before the queen begins laying, as it is what has been done after.

Let me try to answer fully the spirit of your question, for there are some misconceptions likely to be entertained in the minds of beginners. It is a commonly believed opinion that a queen of the current year's rearing is not so likely to swarm as an older queen. The belief is right. And it is wrong. It all depends. Formerly it was held as a sure thing that a queen would not swarm before six months of age. At that time it was probably correct. Lately the opinion is held that a young black queen of the current year will not swarm, but an Italian queen may. There may be some difference between blacks and Italians in this respect, but I'm a little skeptical as to its making

much difference. I think the rule was true of blacks before Italians were introduced—not because they were blacks, but because of the treatment they had.

Before the introduction of Italians, there was little in the way of changing queens, making swarms by dividing, etc. Bees were left pretty much to their own devices. Leave them to their own devices to-day, and you may count that a young queen of the current year's rearing will not swarm till the next season, whether black or yellow. In other words, if a young queen is reared in a colony in the neighborhood of the swarming season, and left in that colony, that queen and that colony will not swarm that season. I'm not so sure that any satisfactory reason can be given, but the fact seems to be well established.

If a queen is reared this season, and after being reared is put in a hive where conditions are favorable for swarming, her age will not prevent swarming. Let a colony be on the point of swarming, or take it immediately after it has swarmed and the swarm has returned: take its queen from it, and give it another queen, and that colony will swarm without regard to the age of the queen. I once had a colony swarm and return (the queen was clipped), and I took away their queen, giving in its place a young queen that had not been laying more than two or three days. Promptly that swarm came out with the young queen not more than two days later—I think it was the next day.

If a queen is so old as to require superseding, and that superseding occurs about swarming-time under prosperous conditions, there is likely to be swarming, whereas there might have been no swarming if a young queen had been present that did not need superseding.

I haven't given you, perhaps, a satisfactory answer, but it's the best I can do.

2. Probably just the same as if they had been put in the nucleus before hatching.

3. Four or five frames of brood well covered with bees would be rather a colony than a nucleus. A queen reared therein might be a very good queen, supposing, of course, she was of good parentage, but such a plan of rearing queens would hardly be advisable if many were to be reared, because too expensive. A number of bees may be reared in one colony just as well as to let the colony rear a single cell, and when the cell is near hatching it may just as well be in a nucleus till the queen lays.

You would probably find Doolittle's queen-rearing book a profitable investment.

4. What would be best for one might not be best for another. For some, natural swarming would be best, preventing second swarms by hiving the swarm on the old stand with old colony close beside it, and removing the old colony to a new location a week later. For some the nucleus plan would be best: Start a sufficient number of nuclei, and from time to time give to each nucleus a frame of brood with adhering bees, or brood only, planning to give just enough help to build each nucleus up to good strength for winter.

5. It would probably make a big difference to give a virgin queen 45 days before the flow—so great a difference that you would not be likely to try it a second time. The harvest with you is likely to begin somewhere about June 10. Forty-five days before that time would be in the latter part of April. As far north as northern Illinois you will hardly succeed in rearing good queens by that time. That is objection enough of itself. To put a virgin queen in a colony April 25th would stop the laying and brood-rearing at a time when it is important to have it pushed to the ability of the colony. That is also a sufficient reason of itself. Neither would it be wise to think of giving a young laying queen in April. It would make chances for swarming somewhat less, but not enough less to overbalance the disadvantage.

Out-Apiary and Swarming Feeding for Winter.

1. How could an out-apiary be managed where daily attention could not be given to it, mainly the swarming question, possibly 25 or 30 colonies, in a fine honey locality? Would the bee-entrance guard on each hive prevent swarming? What would be the result if they did swarm, and were lost, as long as the remainder did well?

2. What would be a fair share (of honey) to give to a person for allowing me to place 10 or 12 colonies on his farm, everything to be furnished by me, he only to see to the shade-boards, etc., as he does not understand hiving swarms or bees at all?

3. What is the best time for feeding sugar syrup, for

winter use? and how can you feed thru the winter in case of necessity? Some time since one colony starved to death for lack of food, not knowing how to feed syrup, but instead I placed super with comb honey on the hive, but it seemed to do no good. They were on the summer stands.

4. Can you name one or two good feeders, and tell how to use them?

5. Can extracting be done thru the winter as well as in the honey season? In fixing frames for extracting, would medium (full sheets) brood foundations be right? and should they be wired in?

In my short experience I have found that the bees in hives not shaded, begin work earlier, and also they work later than those that are shaded.

WASHINGTON BEGINNER.

ANSWERS.—1. Bee entrance guards would not in the least prevent swarming. It only prevents the queen from going with the swarm, and without a queen they would not leave. It would be just as well for them to swarm and be lost "as long as the remainder did well," but unfortunately the remainder will not do as well. Entrance guards might be safely used if you could visit the place as often as once a week, for the queens would be held in the traps awaiting your treatment. Perhaps you might be best suited to have such large hives with so much room in the extracting-supers that the amount of swarming need not be considered.

2. That question is not easily answered, but at a guess it might do to give him honey enough for use on his own table. The amount of compensation would not be exactly in proportion to the number of colonies. A man would just about as soon have 10 colonies sitting on his ground as one. In some cases a man might be willing to pay for having bees on his place for the sake of having his fruit fertilized.

3. Just as soon as you are satisfied no more surplus will be stored. In some places—indeed in a good many places—that might be in the last of August. That gives time to have the syrup well ripened and put in proper shape for winter. In any case, try to have all feeding done before September closes.

In case of necessity in winter, use comb honey or sugar candy, making sure that the food is so close to the bees that they will crawl directly upon it. Don't think of feeding syrup in winter.

4. Root's A B C of Bee-Culture gives the Miller feeder first place if the feeding is to be done on top. Put the feeder on top the same as a super; put in syrup and cover over. If the feeding is done early enough, I prefer a plan that is still less trouble. Put dry granulated sugar in the feeder, and then pour hot or cold water on it. The bees will do the rest. If you prefer to feed at the hive-entrance, the Boardman feeder is one of the best.

5. It is just as easy to extract in winter as in summer, if the combs are just as warm. If kept in a very warm room for 24 hours, you will likely be able to extract. If you can hang them overhead in the kitchen they will stand a good chance for heat.

“The Hum of the Bees in the Apple-Tree Bloom” is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a “hummer.” We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

* The Afterthought. *

The “Old Reliable” seen thru New and Unreliable Glasses.

By E. E. HASTY, Richards, Ohio.

WEIGHT OF NATURAL COMB.

Average weight of natural comb 10 grains to the square inch. Prof. Gillette, page 23. If we call the Langstroth frame 144 inches (usually less from being nibbled away at the bottom) the weight of the wax in a comb will be 1,440 grains, or 14,400 grains in a 10-frame hive. Now, if we assume that the 400 grains will cover the extraneous matter work into the new comb of a hive, we have just an even two pounds of actual wax. Practically, I think they usually work in a good deal more extraneous matter than that; but on the other hand, next to the bars all around there is much more wax than 10 grains to the inch. So a fair estimate of the actual wax in a hive, providing it all could be recovered, is two pounds for 10-frame hives, and one pound $\frac{1}{2}$ ounces, nearly, for the more common 8-frame hives.

MAKING ROOM FOR WAX-SCALES.

And so D. H. Coggs shall think that it pays to cut slices from the combs at extracting-time to give the bees place to use their scales of wax *without building bars*. I think he has a valuable idea—that is, valuable in long, strong runs of honey. When the combs are scant thickness, or not built down at the bottom, or when the honey-flow is short, then the cutting would be rather a waste. Page 24.

FANNING AT THE HIVE-ENTRANCE.

I think Dr. Miller, on page 25, does a pretty good job at theorizing. A bee uncertain about its reception by the guards at a hive-entrance falls to fanning at once—plain way of saying, “Don't you see, I am ready to go to work? and robbers do not work.” Guess it's right. Still, let a fourth swarm come out and leave the parent hive nearly empty and pretty well demoralized as to guards; let the swarm hang an hour, till said hive gets cold—colder than it needs to be; then hive the swarm and carry it away, leaving say 50 obstinate bees determined not to leave the limb. In the course of the day it will dawn upon them what fools they are, and they will return to the alighting-board. I should expect to see them fanning together there the first thing they do. In this case there can hardly be fear, or uncertainty, and there is no need of the fanning being done—what is it? Fanning in the entrance draws outside the familiar smell of home. Perhaps that is what they want—before they have submitted to the inevitable quite enough to go in.

DOUBLE WALLS AND CHAFF ON A HOT DAY.

Mr. J. M. Rankin has got on track of a question that is of value—the actual effect of double walls and chaff on a hot day as compared with plain, single-walled hives. Think the working-force for a time mostly abandoned the supers of the single-walled hives. This is one of the things we want to be sure of before we are too sure of it, so repeated observations by different observers are desirable. For future comparisons Mr. R. should have given us the temperature in the shade in addition to that in the sun. Page 39.

COMB BUILT BETWEEN FINISHT COMBS.

Dr. Miller is right in his answer to “South Carolina,” on page 43, that a comb built between two finisht combs in a super is apt to be very thin. Even if so much extra space is given as to obviate that trouble the alternation doesn't seem to be a good plan. Put one first-rate, finisht comb next one side of the super, then several frames with starters, then one or more partly built combs if you have them, as I mostly do; then fill the rest of the super with finisht combs. That seems to be the “how” to do it, providing you don't want the bother of having them built below.

Queenie Jeanette is the title of a pretty song in sheet-music seen, written by J. C. Wallenmeyer, a musical beet keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

Feeding Bees for Winter.

Our bees went into winter quarters in debt to us. We had to feed about two-thirds of the colonies late in the fall, and unite many weak ones. If we had not fed they would have had very little honey to winter on. A friend about 30 miles from here fed his bees in November to keep them from starving.

We took only about 300 pounds from 140 colonies. We united some in the fall so now we have only 98, but as their fall honey was gathered from decaying fruits, etc., I fear they will not winter as well as they usually do. I am sure they winter better on sugar syrup if fed early and well sealed, than they will on such honey as they gathered last fall.

It has been so dry for the past few years that many bees in this locality have died. Some years our crop has been cut short by people spraying fruit-trees while in bloom.

Mrs. L. C. ANTILL.
Warren Co., Ills., Jan. 21.

Something About Bumble-Bees.

On page 44 I notice a letter written by S. T. Pettit, in regard to bumble-bees in winter. I presume the majority of people think they winter here, but I think differently. I will be 67 years old in three more days if I live so long; I was raised on a farm and still live on one, but I have never been able to find a nest of bumble-bees in winter. When the fall of the year comes, and the weather begins to get cool, I have seen them disband and leave their summer nests. I don't know where they go, but I think the queen goes South. My reason for thinking this is that I have never seen a bumble-bee in the spring until the weather had become quite warm, and the flowers had begun to bloom. The queen starts her nest and increases very fast. If they stayed here all winter I should think they would come out as soon as the weather began to get warm, as do the honey-bees, green flies, and other insects.

There are three sizes of bumble-bees—queens, workers, and drones. The drones have very long bodies and are

RUMELY ENGINES

—either traction, portable or semi-portable represent the greatest value that can be crowded into a machine of this kind. Simple, compact, 20 hp. Unequalled for brushing, will drill, saw, mill, feed, grade, etc. All these and other thrashers, horse powers, saw mills, etc. Illustrated catalog mailed free.

Gleanings in Bee-Culture!

Extraordinary Offer.

Gleanings for Jan. 1st contains these Special Articles:

Queen-Rearing in France,
—by—
Giraud-Pabou

314 queens from one hive.
How it was done.
Illustrated by 3 half-tone engravings.

Candied vs. Bottled Liquid Honey,
by **Chalon Fowls**

Figuring up the profits on bottled honey. Illustrated.

Wintering Bees in Clamps.

(From Bee-Keepers' Review

—by—

W. Z. Hutchinson

Four illustrations.
No one is better qualified perhaps than Mr. Hutchinson to write on this subject. His many years' experience wintering bees in Michigan should give weight to his opinion.

Conversations

—with—

Doolittle

Those who have read bee-literature for years always find Doolittle's writings full of practical information. Those who are not familiar with his writings are invited to read a series of practical articles on general topics relating to bee-culture under the title, "Conversations with Doolittle."

Gleanings for Jan. 15th.

Co-Operative Organized Work.

by **R. C. Aikin**

Its benefits demonstrated: The Colorado Honey-Producers' Association as information scheme; The work of the Association outlined.

An Extracting Outfit, by W. A. Gilstrap

Illustrated.

Mintle's Lightning Section-Folder

Illustrated.

Stray Straws.

—by—

Dr. C. C. Miller.
Every Issue

These "Straws" appear in every issue of Gleanings, constituting one of its most valuable features. Dr. Miller reviews nearly all of the bee-journals published in American and Foreign, and readers of Gleanings get the benefit in these "Straws," thereby receiving much valuable information published in the Foreign journals.

Pickings from Our Neighboring Fields.

by **Stenog, Every Issue**

For several years Gleanings readers have enjoyed twice a month a series of short squibs from this writer's pen. Not only does he give us articles full of value gleaned from other journals, but they are so enlivened by his vein of humor that they are eagerly read by all.

Gleanings for Feb. 1st.

Our Honey-Bottling Symposium.

Fully Illustrated, by

G. A. Deadman,

Earl C. Walker,

and **Walter S. Pouder**

How to wash bottles; Filling with hot honey or cold; Bottles with corks or self-sealing tops; Temperature of honey to be bottled.

The right kind of honey for the purpose; Mixing honeys to secure a flavor; Why honey should be heated in the bottles.

Size and construction of vats for heating the bottles of honey; Tumblers vs. jars or bottles.

The Personnel of the Utter Trial

by **E. R. Root**

A full review of this celebrated case of Utter vs. Utter, or Bees vs. Peaches.

The Belgian-Hare Business.

by **W. K. Morrison.**

of **Devonshire, Bermuda**

A fair statement; Extravagant statements; Bees and rabbits not a good combination.

Co-operative Organization.

by **R. C. Aikin**

Plans outlined; Intelligence bureau; Why simple co-operation fails; Business must be at the bottom; Government's duty; A continuation of this writer's article which appeared in Jan. 15th Gleanings.

Cuba,

by **The American Tramp**

This writer has been in Cuba some two years, and writes understandingly.

SPECIAL OFFER.—Each one of the issues mentioned above should be worth a dime to every beekeeper, but we will send all three for only 10 cents. Hurry along your order before they are all gone.

BETTER YET Send us 25 cents at once, and we will send you Gleanings in Bee-Culture 12 issues, 6 months, beginning Jan. 1st. Feb. 15th will contain several articles on

Cuba,
by **Harry Howe, Robert Luaces,**
and **A. L. Boyden**

Mr. Howe was formerly with Coggshall, of New York, and has already given Gleanings readers glimpses of Cuban bee-keeping. Mr. Luaces, of Puerto Principe, considers that conditions are not well known, and gives information somewhat different from other writers. Mr. Boyden begins a series of articles entitled, "Glimpses of Cuba and Cuban Bee-Keeping," illustrated by photos taken by himself.

Remember, Six months for 25 cents, and your money returned July 1st if you are not satisfied. Mention the American Bee Journal.

10 DAYS TRIAL

Buggy Announcement Extraordinary.

The Kalamazoo Carriage and Harness Co., of Kalamazoo, Michigan, have adopted the plan of sending their vehicles anywhere, on 10 days free trial. They sell direct to consumers at wholesale prices and allow you to take the vehicle from the depot, hitch up to it, try the springs, running qualities, see the trimmings, finish and style before you decide to keep it. No more buying "a cat in the bag, sight unseen." They know the quality of their goods and are willing to let them sell on their merits. Write for free catalogue.

KALAMAZOO CARRIAGE AND HARNESS CO.,

Box 53 Kalamazoo, Michigan.

Maule's (35 new things for 1901) Seed Catalogue

You should, by all means, have this most modern catalogue of modern times. It is brimful and overflowing with good things in vegetable, farm and flower seeds, flowering plants, fruits, bulbs, etc. It contains 35 novelties in vegetables and flowers never offered before, has 116 large plates, seven handsome colored plates and hundreds of illustrations. It gives practical, up-to-date cultural directions and offers many cash prizes. The first edition alone costs over \$30,000, so while we send it free to all customers, we must ask others to send 10 cents for it, which amount they may deduct from their first order. You will make a mistake if you do not write to-day for this the Novity Seed Book of the year. Address,

W. L. HENRY MAULE, Philadelphia.

of the Bee Journal correspondents, but I seem to be as successful with them as the average.

I have taken quite an interest in the different methods of rearing queens, and of introducing them; also caging and sending thru the mails. I have read many of the bee books and papers, and until recently never read any objection to rearing queens on dry sticks, caging them when full of eggs. Some think that a strong colony in the height of the honey-flow is about as good a time to rear a prolific queen as any.

H. T. GIFFORD.

Brevard Co., Fla., Jan. 19.

Nothing but Fall Honey.

Bees did not do much the past season. There was a great deal of white clover, but no honey in it to speak of. We had nothing but fall honey, and very little of that. **W. M. WILSON,**
St. Joseph Co., Mich., Jan. 25.

Light Honey-Flow—Feeding Bees.

The past year was a hard one on beekeepers in this locality. From June 1st the bees did not get a living from the flowers until about the first of September, when the asters yielded

"ELECTRIC" GOODS

Thousands of farmers all over the country know that the name "Electric" stands for the highest quality, the greatest durability, the lowest price. Everything put out of our factory carries the reputation of being "as good as money can buy."

Electric Metal Wheels

of all sizes and varieties, to fit any axle on any vehicle or farm implement, either direct or staggered oval steel spokes.

Electric Handy Wagon,

the neatest, strongest, most durable, easiest to load wagon made. Metal wheels, any width of tire, any height from 24 to 56 inches. Best angle steel hounds.

Tanks of All Kinds.

Sheep Dipping Tanks, Watering Tanks and Feed Troughs of all shapes and sizes.

Trucks

for engines, water tanks, etc. Send for new catalog. We ship our goods anywhere and guarantee to save you money.

ELECTRIC WHEEL COMPANY,

Box 16, QUINCY, ILLS.

some nectar. Some colonies had plenty for winter, but others did not, and I began in August to feed them about 800 pounds of good honey, in order to keep them from starving and get them in good condition for winter. They are wintering splendidly so far, and I hope the coming season will be a good one.

To-day is the worst day we have had so far this winter. It is snowing and blowing, and cold. I hope it will not last long.

A. J. McBRIDE.

Watauga Co., N. C., Jan. 24.

Good Honey-Crop—Introducing Queens.

My honey crop for the year 1900 was 4,500 pounds from 45 colonies, spring count, a little over one-third of which was comb honey. My average yield for 11 years has been 60 pounds per colony, about one-half of it being comb. The best yield was in 1893, when I got 114 pounds per colony, and the poorest yield was in 1899—16 pounds per colony.

Perhaps the method I use for introducing queens will be helpful to some. When I receive a queen thru the mails I put her in a Miller introducing-cage without any of the escort bees, put in some candy, and plug the hole so the workers can not get at the candy. Remove the queen that is to be superseded, and place the cage containing the queen between two of the central combs. The next day open the hive quietly, and if the bees seem friendly to the queen remove the plug, fill the hole with candy, replace the cage, and do not open the hive again for nearly a week. I have had but one failure in five years, in using this method. I formerly lost 25 percent of my queens by following the directions that came with the queens.

I believe many of the failures in introducing are caused by the escort bees being left with the queen. If the bees appear angry do not remove the plug the next day, but wait until they are friendly toward the queen.

The American Bee Journal is all right.

D. I. WAGAR.

Wayne Co., Mich., Jan. 23.

Convention Notice.

California.—The annual convention of the California State Bee-Keepers' Association, will be held in the Chamber of Commerce, at Los Angeles, Feb. 25 and 26, 1901, beginning at 1:30 p.m., on the 25th. Several valuable papers have been promised, and we expect an interesting convention.

J. F. MCINTYRE, Sec.

R. WILKIN, Pres.

The Kalamazoo Carriage and Harness Company's advertisement appears in this issue, making an offer which may truly be characterized as "extraordinary." They offer to send to any reader of this paper any vehicle in their factory on 10 days' free trial, allowing you to use it during that time and thoroughly test it before deciding to keep it. They certainly have unbounded faith in the quality of their goods, or they could not make such an offer. Look up their advertisement and send for Catalog, not forgetting to mention the American Bee Journal when writing.

Great Book About a Great Machine.—The new Cyphers' Locking Catalog is without exception the handsomest and most complete book ever issued in the interest of the poultry industry. It contains 234 pages (8x11 inches) with more than 20 new illustrations representing the highest art of the engraver; the cover is a symphony of delicate gray tints with just a dash of red, and the text is devoted to sensible, practical poultry talk which every poultry raiser ought to read. It is an extremely beautiful

book and as useful and practical as it's handsome.

The Cyphers' Incubator during the four years that it has been on the market, has gained a popularity and achieved a success which is nothing less than phenomenal. And yet, its success is not hard to explain. The American poultry-raisers recognized in the Cyphers the first incubators really built on a scientific plan—a plan which follows nature's method in the diffusion of heat and the retention of the moisture of the egg, and they have found by experience that it is the only incubator which has successfully solved "the moisture question" and "the ventilation question" by absolutely self-regulating in regard to heat, moisture and ventilation. Without question these two great features: self-supplied moisture and self-ventilation, were the original discoveries of Mr. Cyphers, and were brought to a practical working success by him.

The Cyphers' Company puts out with every machine they sell one of the strongest guarantees we have ever seen on any machine of any kind. And the beauty of it is every poultryman in America can rest assured that it means EXACTLY what it says.

We know that every one of our readers will be interested in this magnificent catalog. Send 10 cents to pay postage, and ask for Book 94, Address: Cyphers' Incubator Co., 601 Broadway, New York, N. Y., Boston, Mass., New York City, or Chicago, Ill. Please mention the American Bee Journal when writing.

CAREER AND CHARACTER OF ABRAHAM LINCOLN.

An address by Joseph Choate, Ambassador to Great Britain, on the career and character of Abraham Lincoln—his early life—his struggles with the world—his character as developed in the later years of his life and his administration, which placed his name so high on the world's roll of honor and fame, has been published by the Chicago, Milwaukee & St. Paul Railway, and may be had by sending six (6) cents in postage to F. A. Miller, General Passenger Agent, Chicago, Ill.

6A3t

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Jan. 19.—Honey is selling slowly; this applies to all grades with the exception of white clover and basswood comb honey which sells readily at 16c providing it grades No. 1 or better. All other kinds of white comb honey sell at from 14c to 15c, and graded white comb at from 8c to 10c. Extracted and off-grades of comb, 13c to 14c; amber, 12c to 13c; amber extracted, 7c to 7 1/2c; dark and buckwheat comb honey, 6c to 7c. Extracted, white, 7c to 7 1/2c; basswood and white clover bringing the outside prices; buckwheat and other dark grades, 6c to 6 1/2c. Beeswax, 28c.

R. A. BURNETT & Co.

KANSAS CITY, Jan. 22. Fancy white comb, 15c to 17c; amber, 13c to 14c; dark, 9c to 11c; demand good. Extracted, 7c to 9c; demand quiet. Beeswax, 24c to 26c.

R. CROMWELL PRODUCE CO., Successors to C. C. Clemens & Co.

BUFFALO, Jan. 17.—All kinds of honey are so quiet it is difficult to make a sale. Occasionally some sells, fancy 14c to 15c; few, 14c; choice and No. 1, 12c to 13c; few, 11c; but, 9c to 10c, and all kinds in liberal supply; some may have to be recomended. Extracted, 7c to 8c, and not wanted in Buffalo. Beeswax, 22c to 27c.

BATTERSON & Co.

ALBANY, N. Y., Jan. 18.—Honey market is dull on all grades now, with light stock and light demand. White comb in good condition, not candied, 15c to 16c; mixt, 13c to 14c; buckwheat, 12c to 13c; mixt, 11c to 12c. Extracted, white, 8c to 8 1/2c; mixt, 6c to 6 1/2c; dark, 5c to 6c.

H. R. WRIGHT.

BOSTON, Feb. 8.—Fancy No. 1 white in cartons, 17c; A No. 1, 16c; No. 1, 15c to 16c, with a fairly good demand. Absolutely no call for dark honey this year. Extracted, white, 8c to 8 1/2c; light amber, 7c to 8c. Beeswax, 27c.

BLAKE, SCOTT & LEE.

CINCINNATI, Jan. 16.—Market very quiet. No change in prices. Fancy white combs sell for 16c. Extracted, dark, sells for 5 1/2c, and better grades bring 6c to 7 1/2c. Fancy white table honey brings from 8 1/2c to 9c.

C. H. W. WEBER.

NEW YORK, Dec. 22.—Fancy white, 15c to 16c; No. 1 white, 14c; No. 2 white, 12c to 13c; amber, 12c; buckwheat, 10c to 11c. Extracted in fairly good demand at 7 1/2c to 8c for white, and 7c for amber; off-grades and Southern in barrels at from 6 1/2c to 7 1/2c per gallon, according to quality. Not much demand for extracted buckwheat as yet. Some little selling at 5 1/2c to 6c. Beeswax firm at 28 cents.

Demand continues good for comb honey; supply fairly good. Extracted in fair demand with enough supply to meet requirements.

HILDRETH & SEGELER.

DETROIT, Jan. 19.—Fancy white comb, 15c to 16c; No. 1, 13c to 14c; dark and amber, 12c to 13c. Extracted, white, 7c to 7 1/2c; amber and dark, 6c to 6 1/2c. Beeswax, 26c to 27c.

M. H. HUNT & SON.

SAN FRANCISCO, Jan. 9.—White comb 13c to 14c; amber, 11c to 12c; dark, 8c to 9c. Extracted, white, 7 1/2c to 8c; light amber, 6 1/2c to 7c; amber, 5 1/2c to 6c.

Stocks of all descriptions are light, and prices are being as a rule well maintained at the quoted range. Firmness is naturally most pronounced in the case of amber and smaller sizes of honey, the latter being in very scanty supply.

HONEY MARKET.—We may have a customer with a short distance of you who wants your honey or beeswax. We are in close touch with all the markets; therefore write us regarding your crop, stating quantity, quality, and lowest cash price. References—Either Bank here for any business man in this city.

FRED W. MUTH, CHARLES J. HAUCK,
P. W. J. HAUCK.

One Minute, Please!

We beg to announce that we have gone into the bee-supply and honey business.

Being practical bee-keepers who understand the supply business thoroughly, and know pretty well the wants of the bee-keepers, the firm will give its exclusive attention to the bee-supply business and the promotion of the sale of honey in this vicinity.

After visiting all the important manufacturers, we have selected a line that will give the best of satisfaction. Our location—adjoining the Suspension Bridge—is most central, and being only four blocks south from the Fountain Square, is right down in the business part of the city, and especially handy for our Kentucky friends: our facilities for prompt service are perfect; and our prices are consistent with good business judgment. Our Catalog has many new features. Send us your name so we can mail you one.

AMERICAN BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., FEBRUARY 21, 1901.

FORTY-FIRST YEAR
No. 8.

WEEKLY

HON. A. H. JONES.
Pure Food Commissioner of Illinois.

PUBLISHED WEEKLY BY

GEORGE W. YORK & CO.

144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

IMPORTANT NOTICES:

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, \$1.50 a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec00" on your label shows that it is paid to the end of December, 1900.

Subscription Receipts—We do not send a receipt for money sent as to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

Reformed Spelling.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "th" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

The Bee-Keeper's Guide

Or, Manual of the Apiary,

—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW SUBSCRIBERS for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW SUBSCRIBERS—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

ALFALFA
OR
BASSWOOD

THE BEST WHITE Extracted Honey

ALL IN 60-POUND TIN CANS.

ALFALFA
HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD
HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

We have a good stock of the fine WHITE ALFALFA and WHITE BASSWOOD EXTRACTED HONEY that we can ship by return freight. Most bee-keepers must have sold all their last year's crop long before now, and will be ready to get more with which to supply their customers. All who have had any acquaintance with the above-named honeys know how good they are. Why not order at once, and keep your trade supplied?

Prices of Either Alfalfa or Basswood Honey:

For the purpose of selling again.

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are boxt. This is all

Absolutely Pure Bees' Honey,

The finest of their kinds produced in this country.

Read Dr. Miller's Testimony on Alfalfa Honey:

I've just sampled the honey you sent, and it's prime. Thank you. I feel that I'm something of a heretic, to sell several thousand pounds of honey of my own production and then buy honey of you for my own use. But however loyal one ought to be to the honey of his own region, there's no denying the fact that for use in any kind of hot drink, where one prefers the more wholesome honey to sugar, the very excellent quality of alfalfa honey I have received from you is better suited than the honeys of more market flavor, according to my taste. C. C. MILLER.
McHenry Co., Ill.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

26 cents Cash paid for Beeswax.

low, upon its receipt, or 28 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO.

This is a good time to send in your Beeswax. We are paying 26 cents a pound—CASH—for best yellow.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861 THE OLDEST BEE-PAPER IN AMERICA

41st YEAR.

CHICAGO, ILL., FEBRUARY 21, 1901.

No. 8.

* Editorial. *

Slow Cooling of Beeswax and its effect upon color has attention again in the Bee-Keepers' Review. Editor Hutchinson says:

The American Bee Journal admits that the slow cooling of wax simply allows the dirt to settle, and that is the only way that slow cooling can have any effect upon the color. But it still clings to the idea that the dark color of wax comes from its impurities. Here is where our old friend is making his mistake. The color is in the *wax itself*. Dark wax will remain dark, no matter how slowly it is cooled; yellow wax will be yellow altho so full of dirt that the particles can be seen. Any one who cares enough about this can easily satisfy himself. Let him get a cake of dark, black wax, melt it and keep it in a vessel surrounded by sawdust, so as to confine the heat, and cause it to cool very slowly. When cool it may have a *cleaner* look, the dirt having settled to the bottom, but it will still be *dark*. If you doubt it, just try it.

Next, take a cake of the brightest yellow wax, melt it, and stir into it a lot of the refuse, or slumgum, or dirt, scraped from the bottoms of other cakes of wax; mix these well, then cool it just as quickly as you possibly can. The *wax* will still be *yellow*, but full of foreign matter. Again I say, if you doubt this, try the experiment.

All of which goes to show that there is no particle of difference in actual belief on either side. Our good friend of the Review wants us to say that different samples of beeswax have different colors independently of the amount or kind of dirt in them, so that there may be a very dark color in wax that does not come from impurities. If Mr. Hutchinson will turn back to the first number of this journal for this year, he will find on page 4 this sentence: "There is no desire whatever to deny that two specimens of wax entirely free from impurities may be very different in color." If he had kept in mind that sentence, he would hardly have said, "But it still clings to the idea that the dark color of wax comes from its impurities," for that conveys the idea that all dark color comes from impurities. There is no real difference as to belief at that point.

Let us get right down to where the point of divergence comes. Take Mr. Hutchinson's last illustration—some bright yellow wax melted with a lot of dirt stirred in and suddenly cooled. To make the illustration clearer, suppose a lot of lampblack is stirred into the wax. We both believe exactly the same thing about it. We both believe that the wax that is in the cake, separated from the foreign particles, is, bright yellow, and that altho no yellow color appears to the eye,

the black color is entirely due to the lamp-black that is there. When asked, "What is the color of that cake of wax?" he says, "Yellow!" we say, "Black." Of course, he may say that it isn't the wax that is black, but the lampblack. But we believe our answer is more in accordance with the every-day talk of people. Put the cake of wax before a witness in court and ask him its color. He looks at it on the outside, and then breaks it in two, and he testifies that it is black outside and in. Take a white handkerchief and rub soot all over it. Mr. Hutchinson would say, "The handkerchief is white. The soot only is black." Common people would say, "The handkerchief is black."

If Mr. Hutchinson should contract for a lot of bright yellow wax, and when it arrived he should find it one-fourth dirt, he would hardly feel satisfied if the consignor should say, "That's bright yellow wax, just what I contracted to send you;" neither will he be satisfied if he is told that a fourth will be deducted for the weight of the dirt.

Referring to the issue of this journal for Jan 6th, the American Bee-Keeper says:

"Editor York now asserts that his journal has never pretended to claim for slow cooling anything more than that it allowed the foreign particles time to settle."

We do not believe that Editor Hill is a man who would intentionally misrepresent, but that statement, "now asserts," might be understood to mean that some change had been wrought in the views or the statements of this journal. So far from that being the case, it is true that precisely the same assertion was distinctly made in this journal the first time any editorial belief on the subject was given, as Editor Hill will see if he turns to the issue for Nov. 29th.

Mr. Hill then asks, "Why, then, has the Journal so emphatically opposed our assertion that slow cooling has nothing to do with rendering dark wax a bright yellow?" Simply because the assertion is not believed to be true.

Let us see if we can express, in as few words as may be, just what we do believe. The most of the wax in this country is of a bright yellow if properly cleansed, but when rapidly cooled, as is likely to be the case with the inexperienced, it has mist in it more or less foreign particles that give it a dull or dirty color. If allowed a long time in cooling, it will be kept a long time in that liquid state suitable for the settling of the foreign particles, and thus the dirty-looking wax will become bright yellow.

A Michigan Foul Brood Law. Another attempt is now being made in the Michigan legislature to secure the passage of a law

providing for the appointment of a bee-inspector for that State. Editor Hutchinson, in the January Bee-Keepers' Review, had this to say about it:

Once more have the bee-keepers of Michigan, in convention assembled, appointed a committee to labor for the passage of a needed foul-brood law—a law that will empower the governor to appoint an inspector who has been recommended by the State Bee-Keepers' Association, and who will have authority to destroy foul-broody colonies when the owner can not or will not properly treat them. There is also to be remuneration for colonies that are destroyed, the same as the owners of cattle diseased with tuberculosis are reimbursed for their property when it is destroyed for the general good. A resolution was also unanimously carried recommending the passage of the law, and this resolution will be read before both houses of the legislature.

There was an attempt, two years ago, to pass a similar law, but it failed, principally because of the apathy of bee-keepers. I am informed that only 20 letters were received by members asking them to vote for the measure. The simple introduction of a bill will not secure its passage; the members must be urged to vote for it, and *good reasons* must be given, showing why the measure is needed. It must be remembered that the majority of people know very little about bees or bee-keeping, and the members of the legislature must have explained to them the contagious character of foul brood, how it spreads from hive to hive, and from apiary to apiary, and from county to county, and that it is impossible to prevent this spreading until there is some one in authority to *compel* careless, ignorant or willful bee-keepers to rid their apiaries of the disease.

Members should also have their attention called to the value of the bees to the fruit-grower and horticulturist by their work in fertilizing the blossoms. The loss to the country from this source would be even greater than the loss to bee-keepers. If bee-keepers will only wake up and do their duty in this matter, the bill can be past. There are hundreds of bee-keepers in this State, and yet only 20 of them had sufficient interest in this matter to write to their representative and ask him to vote for this measure, giving the reasons why the law is needed. If there is no foul brood in your apiary, it may be in your neighborhood, nearer than you think. You little know how soon you may need help.

In order that the bee-keepers of Michigan, who should be more interested in this matter, may know just who are the members of their State legislature, we append a list herewith. When writing your senator, address him, "Senate Chamber, Lansing, Mich.," address your representative, "Representative Hall, Lansing, Mich." Do this at once, and besides giving reasons why the law should be past, let him know that you fully expect him to use his influence and vote in favor of it.

Weekly Budget

NOTES ON THE WISCONSIN CONVENTION.—As we promised last week, we will now endeavor to put down a few notes concerning the recent annual convention of Wisconsin beekeepers, which was held at Madison, Tuesday and Wednesday, Feb. 5th and 6th.

By previous arrangement, at 3 o'clock Monday afternoon, Editors E. R. Root and W. Z. Hutchinson, with the writer, met and boarded the comfortable Chicago, Milwaukee & St. Paul train at the Union Depot here, and started for Wisconsin's fair capital. We arrived about 8 p.m. and "put up" at that famous farmers' hostelry, known as the "Simon's House." Here is where the beekeepers and other devotees of rural industries usually stop. And the boarding is good; but the sleeping—well, we have seen downier and sweeter resting-places.

Mr. N. F. France, the energetic and enthusiastic president of the Wisconsin Association, was the first of the clan to meet us in the hotel. He had reserved for the "three editorial boys" a room with two beds. But it was too late for supper at the hotel, so we had to look up a restaurant, and were directed to one which seemed to be patronized by State senators (the legislature being in session), so at least two-thirds of the editors were satisfied! After disposing of three hot oyster stews, the journalistic trio returned to the hotel, where Editor Root began a lengthy nocturnal convention with Mr. France in the waiting-room, while Mr. Hutchinson and this "little editor" went to their third-story room and retired, each taking a bed, and remarking that when Mr. Root came up we'd see which bed-fellow he'd choose. (Mr. Hutchinson "got the mitten" that time, if never before in his life. It's an advantage to be small in size sometimes.)

As we expect to publish a report of the convention—especially the excellent papers read—we will not dwell very much here on the meeting. We do want to say, however, that Mr.

France is a splendid presiding officer of a beekeepers' convention. He keeps things going, and in a very interesting way. As A. I. Root was recently called the "Poobah" of American bee-keepers, Mr. France well deserves to be called the "Poobah" of Wisconsin beekeepers.

The first or Tuesday, evening, was devoted to a stereopticon lecture by Editors Root and Hutchinson, one manipulating the slides while the other explained the pictures. This was a most successful feature of the program, and one which was thoroughly enjoyed by all present.

Editor Hutchinson had previously planned for the taking of a photograph of the "editorial triplets," so on Wednesday morning we three called on one of Madison's best "photogs," and engaged him to do the job. As each of us had on a queen-bee button, he "caught on," and persisted in calling Mr. Hutchinson the "king-bee," presumably on account of his (Mr. H.'s) height and dignified appearance. We understood afterward that we were also taken for three senators (!) by the lady clerk who entered the order for the sitting. (We all survived, however.)

At 1:15, on Wednesday, Mr. Root and the writer decided to take the train for Watertown, and call on the G. B. Lewis Co. Mr. Hutchinson was to follow on a later train, by another route, and meet us in Milwaukee in the evening, and then all three go on to Chicago.

Neither of us had been to Watertown before. We arrived at 2:30, and immediately went to the office of the G. B. Lewis Co. We found Mr. George C. Lewis, the affable manager, "at home." He is the worthy son of Mr. G. B. Lewis. He gave us a cordial reception, and showed us all over their great factory, where hives, sections, basket boxes, etc., are turned out in any quantity desired. It was both surprising and interesting to see how rapidly the basket boxes are made by machinery in the hands of bustling boys.

About an hour before leaving, Mr. Lewis ordered a two-seated sleigh and a pair of high-stepping black horses, with merry bells, and gave us a ride in the bracing air of Watertown. We saw pretty much the whole town, which covers nine square miles, and has a population of about 10,000 people. It is a delightful place, and if Mr. Lewis is a sample of its inhabitants, it is all right.

Just before taking the sleigh ride, we called on the firm of Woodard & Stone. They are large manufacturing confectioners and bakers, employing from 50 to 75 hands, many of them being girls. They use a great deal of honey in their enormous business, and prefer Wisconsin honey. They list over a dozen things in which they use honey, viz:

Urban wafers, honey-bir (died), honey-cake (died or plain), honey coconut-cake (died), honey flavors (died or plain), honey fingers (died or plain), honey coconut fingers (died), honey gems (died or plain), honey coconut gems (died), honey jumbles, (died or plain), and honey coconut jumbles (died).

We had the pleasure of meeting Mr. Stone, who was enthusiastic over the use of honey in the preparation of good things to eat that are baked. He is an earnest advocate of pure honey, and will have no adulteration. He knows of no other sweet that can possibly take the place of honey when it comes to keeping a cake or cookie moist and good for a long time.

We saw a number of samples of their honey goods, and all were nice and tempting.

One of the genial employers in the office was very kind in taking Mr. Root and the writer all over the factory, showing the making of candies and baking of crackers, etc. One machine and oven consumes 40 barrels of flour a day, which makes nearly 200 barrels of oyster crackers.

One of the many things that impress us, was the happy looking boys and girls that were working there. All seemed to enjoy their work. May be it was because of the sweet business in which they were engaged that day—making candies of various descriptions! Their motto might well be that of the bee-keepers: "Our toil doth sweeten others."

As agreed, Mr. Hutchinson joined us in Milwaukee, and we all arrived in Chicago again before 10 p.m. Editors Hutchinson and Root took a late train for Lansing, Mich., expecting on the following day to aid in securing the passage of a foul-brood law in the legislature now in session there.

Well, our Madison-Watertown trip was a very pleasant one, and afforded the writer a much-needed change and rest after a most trying month following the fire on Jan. 1st, and the subsequent moving to a new and improved location, where we will soon be all settled and running as if nothing unusual had happened.

MR. EDGEE SECOR, general manager of the National Bee-Keepers' Association, desires us to make the following statement in these columns:

In my annual report in December, 1900, the financial statement says that Mr. Abbott received \$41.25 for expenses in attending the Pure Food Congress. This is a little misleading, and in justice to Mr. Abbott I wish to say that \$10 of this amount was subscribed by him toward paying the expenses of attending the Pure Food Congress. Consequently the amount he received for his expenses was only \$31.25, which was probably a good deal less than he actually spent. The statement should have shown those items separately, which it failed to do.

EDGEE SECOR,
General Manager

MR. J. M. HARRISON, writing from San Diego Co., Calif., Jan. 27th, said:

"We have been having very reasonable weather so far, and the outlook is superb for another year. A fine rain to-day."

EDITOR WILL WARD MITCHELL seems to be a very busy man, if we may judge from a short editorial paragraph in the *Progressive Bee-Keeper*. He says that besides his work on that paper, he issues a small weekly, writes for several publications (preparing for the future now), gets out from 50,000 to 100,000 catalogs each year, with job work galore, reads the latest books with Mr. Leahy (who is a delightful critic), acts as secretary in two

lodges, superintends a Sunday-school, teaches a class mostly of teachers, and, in fact, is not burdened with idle hours. He hopes soon to catch up with his work, now that his eyes are better.

We wonder that Mr. Mitchell has any eyes left at all. We do not see how he can do anything well when he attempts to do so much. The trouble with most busy men nowadays is that they attempt to do everything, or else in some cases there is an attempt made to put almost everything on the busy man. Of course, the busy people are the only folks who do things. They plan their work, and are thus able to do many times more than people who do not plan to use their time wisely. Mr. Mitchell would better go slower and thus live longer to help his fellow men.

MR. THOMAS G. NEWMAN, as most of our readers know, during the past year, on account of physical weakness and defective vision, has been unable to read and write. In the number of his *Philosophical Journal* for Feb. 24, he says:

"With improved physical health the editor is now able to resume editorial work, and fully expects the return of vision at no very distant day."

All our readers will be pleased to know of the prospect there is for Mr. Newman to have the full use of his eyes again.

No. 4. Extracted Honey Production.

Can not Produce Both Comb and Extracted from Same Colonies—Limited Swarming Best—About Equipment—How to Make a Strainer.

BY R. C. AIKIN.

IT is practically out of the question to produce both comb and extracted from the same colony. I know it is possible to do it, but in an average field and in the hands of an average apiarist, it can not be made a success. Some of the things necessary to get both and be a success, would be a sure and positive flow, lasting long enough and of sufficient quantity to fill the sections put on. A flow giving two or more supers, may be taken part in each form by allowing the sections to be well nigh completed before adding the extracting-super, or by lifting the latter and giving sections under it. But the job is beset with so many difficulties, I would say let none but experts undertake it. I will give up trying to tell how to do it.

I have already told you something about size of hives and their manipulation in building up colonies before the flow, and also somewhat about control of swarming. I will repeat, if you want best work and most honey obtainable where flows are somewhat uncertain and of short duration, the less swarming the better. This applies more fully to summer flows—a fall flow is different because one has all summer to build up and may be able to double, treble, or quadruple the number of colonies and still have good working ones.

There are other things besides bees and hives needed in producing extracted honey. A honey-house becomes a necessity even when the apiary is very small, tho of course if one has only a half-dozen colonies or so, a small room or tent may be used in lieu of a honey-house specially built for the business, particularly when comb or section honey is produced; but when extracting and producing from 15 or

more colonies, a room should be equipt for this alone. Extracted-honey production needs a larger equipment of tools and appliances than does comb, and needs more care and labor in getting it into proper shape for market. So far as the handling of the two products (comb and extracted) is concerned, there is more labor in the extracted, but in the preliminary work or management of the bees the comb takes both greater skill as an apiarist, and more labor. But I am not discussing the comparison of the two, hence will continue my subject.

Of course you want an extractor. As to whether a 2 or 4 frame machine, I think there is no very great economy in using the larger. I have used for many years a 2-frame machine, and now have a 4-frame one. I do not think I would go back to the 2-frame one; I consider the 4-frame size enough better—especially for extensive producers—to justify its use. If crank help is not convenient and cheap, the larger machine has the advantage. I would also use a reversible.

The extractor should be set solid that it may not shake.

Uncapping and Extracting Honey.

It should also be conveniently arranged to get combs into and out of, having the uncapped combs where the crank-man can reach them easily. I have my uncapping arrangements to the right of the extractor, and just far enough away that there is room between it and the box that receives the cappings to have a rack or hive to receive the uncapped combs. Therewith present photographs of these fixtures as I have them set in my honey-house. The combs to be uncapped are to the right of the knife-pan, and when uncapped are past to the left to a receiving rack right close to the crank. This rack does not appear in the picture because it is down behind the capping-box. Immediately to the right of the capping-box and hanging on or attached to it, is a small trough-like vessel containing water in which the knife lies when not in use. A small oil-stove keeps the water hot. A hot, wet knife cuts better than a cold, dry one.

The bottom of the capping-box is prepared with an incline to one point where is an outlet, and above this is a false or secondary bottom made of wire-cloth of 4 or 5 meshes to the inch, galvanized wire just like the extractor screens. The cappings drop upon this screen and drain thru to the outlet and the honey passes off at once.

Just beneath the uncapping-box, and extending from under it to the left clear to the extractor, is my strainer-

Uncapping Honey.

box. This is made of lumber about a foot wide, using 4 pieces, two of them 6 feet long and the other two about 20 inches. The short pieces or ends are gained into the sides about 1½ inches from the end, the gains about ½-inch deep and about ¼-inch narrower than the thickness of the end pieces that are to go into them. The ends of the end boards are then beveled down this ¼, so that when the box is put together, and driven and thoroly nailed, the joint becomes tight and will leak neither honey nor water. A precaution may be taken by putting white lead or linseed oil in the groove or gain before putting together; this makes a closer joint and prevents decay.

The bottom of this box I make of galvanized iron or of tin. The box can be made any size desired I have made two or three of different sizes, usually the width to correspond to the width of the tin or iron that is to make the bottom, and as long as desired. The metal for the bottom should be enough larger than the outside measure of the box, so that it will project beyond the wood ¼ to 1 inch, this projection to be turned up and pounded snug up against the lumber, after the iron is nailed on. The metal is laid on the box and nailed with flathead 1-inch or 3-penny fine nails, driving them about every inch. Do not drive the nails in a straight row, but zigzag them or alternate, one near the outer side of the board, and the next near the inner side, just so there is no danger of missing the wood.

After it is nailed, take a strip of about ⅝ or one inch thick—you can make these by ripping out from the edge of a board. Nail this strip over the metal bottom clear around, using about 6 or 8 penny nails and driving right thru the metal into the edges of the sides and ends of the box.

These strips are not really needed to hold the bottom on—they serve another purpose. You see, if you should fill your box with honey and attempt to lift it, or have it set in such a way that there was no support under the bottom, the weight would sag the bottom more or less, the sides springing in as the bottom sagged. After these strips are nailed on—the box being mouth down, of course, while you are doing the nailing—you really have a little box just the depth of the thickness of the strips. Now cut one, two, or three strips as long as the inside width of the box, and 1½ or 2 inches wide, and the same thickness of the strips nailed around. These strips are to be just long enough to drop in tight across the bottom between the rim strips, and nailed thru the rims into their ends, nailing from the outside. These cross strips put in tight give the bottom a strong tension and prevent any sag. The rim and strips also support the bottom just their thickness from whatever set upon, and shield the tin or iron from being dented or bruised from any hard substance beneath.

This strainer-box also has a sub or false bottom made this way: A wooden rim or frame is made of strips about 1 inch by 1½, and one or more strips of the same size and length as the ends put across spaced equidistant from the ends. Upon this frame is nailed a sheet of galvanized wire-cloth such as is used in the extractor-baskets. This screen is then placed in the box, being in its outside measure just scant the inside of the box, and rests on little cleats nailed to the sides of the box 2 or 3 inches above the bottom. On this false bottom or screen, spread a piece of cheese-cloth that is big enough to cover the whole top of the screen and reach up and lap or hang over both sides and ends a little, and you have a very good and complete strainer. When the cloth becomes clogged, remove and wash it.

Larimer Co., Colo.

Bee-Keepers and Bee-Supply Dealers.

An Inquiry Into a Matter of Equity, in the Court of Public Opinion.

BY "COLORADO."

I WILL restate the proposition because I failed to convey the exact point to the dealers in my first letter, on page 69. At any rate they did not get my idea fully.

THE QUESTION.

The excellent and only safe rule of buying bee-supplies for cash enclosed with order affords unequal measure of protection, of justice, of equity, to the two parties to the transaction. The rule makes the seller absolutely safe, but leaves the buyer to carry numerous risks—risk of error in count, risk of unsafe packing, risk of error in cutting, risk of destruction *en route*, risk of misreading or misapprehending the order, and other risks. Can the dealers and buyers devise a rule that will be equally fair, and equally protective to both parties?

THE ARGUMENT.

I am not prepared to offer a substitute. But I am studying the question.

Dadant says no rule can be laid down. I fear this is true. But this view is not creditable to our intelligence. Most of the dealers drop into a discussion of giving credit to buyers. To this extent they misapprehend the point of my query. Plainly, there should be no credit. The only route to right prices is under a spot-cash rule.

I do not ask you, Mr. Manufacturer, or Mr. Dealer, to surrender an ounce of the protection that you have. But I want an equal share with you.

If the buyer parts with his cash weeks before he gets his goods, the rule is not a spot-cash method for the buyer.

Experience has taught me something about writing orders. If I instruct the dealer to fill my order within a certain time, or else return the inclosed remittance, I invariably get prompt attention. Otherwise I may wait indefinitely, altho the dealer may have my cash. We buyers often fail to state our wants clearly.

Commercial honesty—I mean the ethical code governing business men—is superior to individual honesty. I

would not sell supplies, or other goods for that matter, on credit at all—except where satisfactory guarantees exist. And I doubt the wisdom of any exceptions at all. Some individuals are small, querulous, mean, unreasonable. These must be avoided.

To ship supplies—the same to be paid for after inspection and approval by the purchaser—would be more satisfactory than the requirement to pay in advance. Even fair, reasonable, capable men might differ as to the merits of goods. But if both want to do right, they will reach agreement.

I do not concur in Mr. Dittmer's paragraph as to publishers, if he means just what his language seems to convey.

Mr. Root's advice to deal thru a wholesale house, in my own State, is objectionable because involving needless expense. I will prove this at another time. Questions of locality and local freight charges enter in.

I demur to Mr. Falconer's remark that one who produces honey and sells it "is not in business." There is no reason why a little class of people with names in commercial reports should entirely monopolize the title, "business men."

But enough for to-day. A few neighborly remarks in the future, perhaps.

Do Bees Puncture Fruit?—Not Their Nature.

BY PROF. A. J. COOK.

I HAVE received from Hon. Eugene Secor, general manager of the National Bee-Keepers' Association, the following interesting correspondence:

Prof. A. J. Cook—

Dear Sir:—I send you a copy of a letter received from Prof. Slingerland, of Cornell University, New York. I would like to know how you coincide with the opinion of his senior professor regarding the structure of the bee's mouth. I have been led to think differently. I had been intending to send Prof. Slingerland as an expert witness in a case we have in New York, but, after receiving this letter, I changed my mind and did not ask him to go. I will rely on your statement of the case whether you agree with him or not. Yours truly,

EUGENE SECOR.

The following is Mr. Slingerland's letter to Mr. Secor:

ITHACA, N. Y., Nov. 20, 1900.

MR. EUGENE SECOR,—

Dear Sir:—Yours of the 11th inst. at hand. I enclose a copy of my Rural New Yorker article. This is as far as I can go in the matter. I have no original data to offer, and I do not feel competent to testify regarding the capabilities of the mouth-parts of the honey-bee to bite.

Prof. J. H. Comstock, head of the Entomological Department, is as competent as any one in the country to testify regarding these points. He has kept bees and has taught the structure of their mouth-parts for years. For me to prepare myself sufficiently to testify with knowledge would require more time than I am devoting to it. With Mr. Benton, I do not think you will have any trouble to reverse the verdict of the lower court. I do not know enough about the mouth-parts to help you any.

I have just seen Prof. Comstock, and he says that he sees no reason from what he knows of the mouth-parts, why a honey-bee should not be able to bite into a grape or peach. Hence, I doubt if you could get desirable testimony from here.

Sincerely yours,

M. V. SLINGERLAND.

I regret that these letters were mislaid during my absence from home and have but just come to my notice. Of course it is too late to be of any use in the lawsuit which was then pending. It is, however, a matter of such general importance that a full consideration of the subject will not be out of place.

I fully agree with Prof. Slingerland, that no one in the country is better qualified to give an opinion in general matters of entomology than is Prof. Comstock. I do not wonder that he made the remark that he could see no reason from the structure of the mouth-parts of the honey-bee why it might not be able to bite into grape or peach. I should greatly hesitate to state that a bee could not puncture ripe fruit. I think Mr. Benton made such a statement in the suit referred to. I am rather inclined to the opinion that they could do so if they only knew their ability and had the curiosity to prompt the quest. I am, however, entirely certain that bees never do bite into fruit. They never attack any fruit until the oozing juice calls them to this luscious banquet. It simply is not their nature to do so. They are only attracted by odors in connection with color, and without the odor they would ever leave the fruit unmolested. If the skin of the fruit is intact, the odor is retained and the bee makes no visit. It certainly is the habit of bees ever to

leave unmolested any and every sealed vessel like sound grape, cherry or peach.

I presume I have experimented more in this direction than any one else in the country, and therefore I may claim with some assurance the ability to give a correct judgment in the matter. I have repeatedly taken clusters of sound grapes that were very ripe, and pierced certain of them with pin or needle so that the juice would ooze out, and then placed them near the hive, or upon the alighting-board of the hive, and often upon the frames above the cluster of bees within the hive. This was done when there was no nectar to be gathered in the field, at which time, as every apiarist knows, the bees are ravenous to gather from any possible source. The bees would suck the wounded fruit but leave every other grape entirely untouched. This was done over and over again, and always with the same results. The bee has a large brain for an insect, but, brainy as it is, it seems unable to form a judgment in the matter of the coveted juice if the latter be sealed up by the skin of the grape.

Every grape-grower has observed at some time when the grapes of the vineyard are very ripe, and when the weather is sultry and humid, that all at once the bees will rush to the vineyard and commence to sip juice from the grapes in great numbers. Of course, in such a case the presumption would be that the bees had bitten into the grapes. Examination proves, however, that this conclusion is utterly at variance with the truth. The overripe grapes affected by the sultry, humid atmosphere, were ruptured, and the tiny droplet of oozing juice hailed the eager bees and they rushed to the vintage with one accord. No wonder the vineyardist blamed the bees. The truth blamed the vineyardist, as he should not have allowed the grapes to become so overripe. In such a case, I have hung sound grapes among those visited by the bees, and not one was touched.

Some years ago, I was lecturing in the famous fruit region of South Haven, Mich. In my lecture, I stated the truth that bees never bite into fruit, and never attack the fruit to sip the juice, except that bird, wasp or Nature had set the latter to flowing previous to the visit of the bees. Many fruit-growers present were vehement in opposition to my view. They were certain that the bees would attack and eat into sound fruit. They had already expressed the wish that I would come the following summer and lecture to them again. I had expressed the fear of my inability to do so on account of college duties. I gave them an account of my experiments as given above, and said that I was not sure that bees could not eat into grapes. I was absolutely certain that they did not. They said that if I would come the next autumn they would prove to me that I was wrong. I replied that I would surely come; that they might telegraph to me at my expense, when I would take the first train. I added, however, "Look closely before you send the telegram, for if I show you after I come that I am right and you are wrong, then I shall want not only expenses, but pay for my time." Many present said, "We'll have you here next autumn."

The telegram never came. I lectured there afterwards many times, and was gratified to find that the opinion on the question was entirely changed. The pomologists were one with me in the matter.

Some years later, I was lecturing in the grape-growing region of Sandusky, Ohio, where there was almost an exact repetition of my former experience at South Haven, Mich. The Sanduskians sent no telegram, but repeated my experiments, only to become convinced that I was right.

It may be asked how I can be so certain that bees never do puncture grapes, when I acknowledge a possibility that they might be able to do so as far as the anatomy of their jaws is concerned. Bees, like all other animals, not excluding ourselves, are creatures of habit. Our fathers, not many generations since, put a stone in one end of the meal-bag to balance it on the horse. They simply didn't think that meal as well as a stone could balance meal. While I feel sure that bees think a little, they are away behind us in this respect. Their every habit leads them to peer into the flower-tube in search of the precious nectar. They never go in quest of the sweet unless the escaping odor summons their presence. It is easy to understand why, with their limited thought and meagre reasoning powers, they never go peering into grape or other fruit so long as the same are sealed. Once let the juice ooze out of apple, pear, peach, cherry or plum, and they are not slow to hasten to orchard or vineyard that they may stay the waste. It is not, then, a practical question whether they can or cannot pierce the tender skin of overripe fruit. They never do so. And so

their ability, had they the sense to act, is not a matter of importance.

In California, where fruit-growing is so important an industry, this question has called forth not a little discussion. It has often given rise to hard feeling, and, in a few cases, to expensive lawsuits. I am glad to say, however, that here, as has long been true in Italy and Switzerland, the fruit-growers are beginning to understand that the bees are sometimes an annoyance, they do not attack sound fruit, and are invaluable aids in fruit-growing. Their good work in pollinating the flowers is of inestimable value. The fruit-grower, if anything, is more benefitted by the mere presence of bees than is the apiarist by the close proximity of the orchard.

Los Angeles Co., Calif., Jan. 21.

Spraying Fruit While in Bloom.

Valuable Experiments Conducted at the Geneva Experiment Station, New York.

BY ERNEST R. ROOT.

AT the convention of the New York State Association of Bee-Keepers' Societies, held in Geneva on Jan. 9th, we had the very great pleasure of listening to an address by Prof. S. A. Beach, of the Geneva Experiment Station, detailing a very interesting series of experiments that were instituted to determine the advantage, if any, of spraying trees *while in full bloom*. These investigations had been requested by a certain class who believed that spraying during the time that the trees are in full flower was essential to the best development, growth, and maturing of the fruit. Prof. Beach called attention to the fact that a certain manufacturer of spraying outfits, had sent circulars broadcast over the country, advocating and urging the administering of poisonous mixtures during the time that bees work on trees. Then there were also some among the fruit-growers of New York who advocated spraying at such times, but who could not carry into effect such practice because a law had been enacted in 1898, making it a misdemeanor for any one to spray during the time the trees were in bloom. Some of the fruit-growers (not all) sought on several occasions to have this law repealed; but being foiled they finally secured the passage of an amendment which provided that trees might be sprayed during blooming-time for *experimental* purposes. The object of this amendment (and it appears the bee-keepers did not object to it) was to determine whether there was any advantage in spraying when the trees were in full bloom, irrespective of any damage that might accrue to the bee-keeper. As a result of this amendment a series of experiments was begun at Geneva, and also at Cornell.

In the conducting of the experiments, Prof. Beach stated that several questions were kept in mind: What was the effect of spraying while the trees were in bloom? did the spraying at such times affect the blossoms? did it kill the pollen? and if not, did it affect the setting or the development of the fruit? what part did the bees play in the matter?

Some bee-keepers, he stated, were inclined to make sweeping assertions to the effect that no fruit could set without the agency of the bees. This was altogether too strong a statement. That bees did play a most important part in the fertilization of some kinds of fruit-trees could not be denied. That question might be considered settled.

In the experiments that had been conducted, it was found that the blossoms that were sprayed just at the time they were in full bloom were either killed or injured. If the spraying were administered only during the blooming-time the poisonous mixtures did not go to the right spot, in a good many cases, for the simple reason that no cluster of apple-blossoms, for example, opened out at one and the same time. Some blossoms would be closed, and impervious to the effect of the spraying-liquids; and if no more spraying were administered after blooming-time, then these blossoms that were not open would not receive the benefit, and the fruit-eating insects would then get in their work. The professor brought out the point clearly, that if spraying were applied before blooming and after, the leaf-eating insects in the other, would be destroyed.

He further showed that the spraying-mixtures are exceedingly harmful to the development and growth of the delicate pollen. Some pollen was gathered and taken into

the laboratory and mixed with a thin syrup, then afterward a quantity of spraying-liquid was applied, of about the strength that is used in spraying trees. It was found in every case that the pollen failed to grow. Then the spraying-liquid was reduced 50 percent, and still mixed with pollen and syrup which had been prepared, and still the pollen-grains failed to grow in most cases. The professor said he was decidedly of the opinion that spraying during blooming time was exceedingly harmful to the delicate reproductive organs, and to the pollen itself in the flowers of the fruit-trees. He referred to a certain Mr. Kellogg who had tried spraying strawberries while they were in bloom, and much to his sorrow. He mentioned a number of instances of fruit-men who formerly had believed that spraying during blooming-time was the correct practice, but now had been completely converted.

In the experiments that were conducted in four orchards located in different parts of the State, a certain set of trees were set apart and sprayed while in bloom, and only then, and others were not sprayed. Even tho the bloom was exceedingly abundant, it was found that those trees that were *not* sprayed during blooming-time yielded from a third to a bushel and a half more of fruit. In some cases they sprayed a half of one tree *several times* during blooming time, leaving the other side of the tree not sprayed. There was a marked difference in the setting of the fruit on the two sides of the trees, and that difference was decidedly in favor of the side not sprayed. Experiments were conducted in fruit-orchards in different parts of the State; and in one instance, at least (the Professor would not give the name) a certain fruit-man who believed that spraying during blooming-time was the right thing to do, estimated, after he had sprayed his whole orchard at such time, that he had lost nearly a thousand dollars. He had had enough of that business.

The Professor stated, however, that there was one instance when spraying right during blooming-time might prove to be advantageous; and that was, to kill the apple-scab that might come on at just that time; but even in such a case it has not yet been proved that spraying before and after bloom may not be equally efficient. But, generally speaking, the conclusion seemed to be that spraying during blooming-time was not only wasteful but decidedly harmful as well, cutting down the supply of fruit to an extent that, if generally practiced, would amount to thousands of dollars to the fruit-men all over the State.

On the evening of the first day we listened to an excellent address from another professor of the same station. Prof. V. H. Lowe. The experiments that had been conducted under his direction were for the purpose of determining the value of insects in pollinating fruit-blossoms. A certain set of nine small pear trees it was not practicable to use large ones were enveloped in a hood of sheeting. This hood was large enough to slip down over the whole tree, something in the form of a bag—the bag tied at its bottom around the trunk of the tree. The object of this was to keep out insects, ants, bees or anything that might assist in pollinating the blossoms. For the purpose of ventilation, some windows were made in the sheeting, and the openings covered with a fine netting. On all of these trees so covered, there was a large number of buds, and all the conditions were favorable for a good crop, except that the flight of insects was entirely cut off. Now, then, for the results:

Out of the whole lot of trees covered, there was just one fruit. On another set of trees not covered there were 145. In the other case, where it was not practicable to envelop the whole tree, one large limb, for instance, would be enclosed in the bag, the mouth of the bag being tied around the trunk of the limb. In one such instance there were 2483 buds of an apple-tree that were thus covered with the sheeting. Out of that number just one fruit matured. There was plenty of fruit on other portions of the tree where the limbs were not covered. In one case, where the sheeting broke open so that insects could get in, there were 13 perfect fruits from 818 buds. It was clearly shown that bees or other insects play a most important part in the pollination of average fruit-trees.

When the Professor was asked how much of this pollination was attributable to bees and how much to other insects, he said he could not tell; but Mr. O. L. Herschiser, in referring to a similar set of experiments made some years ago at the Michigan Agricultural College, showing the same results, said that the bees were altogether the earliest insects out; that at the time the average fruit-tree is in bloom it is too early in the spring for other insects to be of any value. In his opinion the covering of the limbs or the

covering of the whole tree as explained by Prof. Lowe (with the result that little or no fruit had set) showed clearly that the bees, and they alone, did the mixing of the pollen.

At the conclusion of both addresses, both professors were given a most hearty vote of thanks for the interesting and valuable testimony they had produced; and this testimony was the more valuable because both men began these experiments at the solicitation of the fruit-men, anxious to show that spraying during blooming-time was not detrimental but decidedly advantageous. Verily, the bees in York State have been and are being vindicated on every hand.

President Marks said he had made the statement that 95 percent of the bee-men of the State were also fruit-growers. He wisht it understood that a large number, yes, the majority of fruit-growers, acknowledged that the bees were their best friends; that it was only a few of the fruit-men who were at variance with the bee-keepers; that there was no real fight between bee-keepers and fruit-growers. Gleanings in Bee-Culture.

Convention Proceedings.

Report of the Proceedings of the 31st Annual Convention of the National Bee-Keepers' Association, held at Chicago, Ill., Aug. 28, 29 and 30, 1900.

BY DR. A. B. MASON, SEC.

(Continued from page 104.)

LAST EVENING SESSION.

The convention met at 7 o'clock, with Pres. Root in the chair.

Pres. Root—The pure-food commissioner of Illinois, the Hon. A. H. Jones, is present, and will address us. I have asked Mr. York, the president of the Chicago Bee-Keepers' Association, to introduce him.

Mr. York—Some other States have been heard from, but finally Illinois has caught up with them. For a long time we worked to organize a Pure Food Commission in this State, and succeeded at the last session of the legislature, when the new law was past which provides for a pure-food commission. It was our pleasure at the meeting of the Chicago Bee-Keepers' Association last December, to have with us the pure-food commissioner who spoke to us and who made such a very favorable impression upon us. We were very thankful to have him with us then, and we assured him we would stand by him in his work to put down the adulteration of food, and I think I can say to him to night the same thing that we did then—we as bee-keepers will co-operate with him in his work, and do all we can to help him make it a success. It gives me very great pleasure to-night to introduce to you our pure-food commissioner, the Hon. A. H. Jones. [Applause.]

ADDRESS OF PURE FOOD COMMISSIONER JONES.

Mr. Chairman, Ladies and Gentlemen:—

When I look over this vast audience, and know the cause in which you are gathered, it affords me pleasure to be here this evening to address you; for if there is anything that is dear to the human heart, it is something good to eat. That is what we are all striving for, to get the very best product we can; and if there is anything better than honey—real good, pure, old-fashioned honey—we have not yet discovered it. [Applause.]

There has something been said about the Illinois State Pure-Food Commission; if there is anything on the part of the commission I can say, it is also for my friend, Dr. Eaton, the State Analyst; if there is anything that will build up this cause more than another, it will be the State Food Commission. You have here, as I can testify, a very zealous friend in Dr. Eaton. The reason why I speak of that, is that all these food products come to him for analysis, and he must pass upon them. Now, I suppose that a good many of you who have been rather like good old Jacob of old, wrestling with the bee-question, have not thought of what a pure-food commissioner and a State analyst

have to do. Think of it! When you look around over all the vast products of the State and see what we have to encompass, it is almost beyond imagination. You can hardly appreciate what we have to do; but I want to say to you that we have the fellows who are manufacturing these adulterated products. I don't care whether it is honey, I don't care whether it is maple sugar, or what it may be—we have them, in the State of Illinois, on the run. [Applause.] And we are going to keep them on the run. [Applause.] I had the pleasure last January, the latter part of it, as I recollect the time, of meeting with the Retail Grocers' Association of this State, down at Rock Island. There were 1200 or 1500 of them. I want to illustrate about how we are doing this in Illinois. After I had talked to them for a day or so—you know that is a good while—and we had gone thru the law and exhausted it, and the rulings, I said to them, "Now, gentlemen of the Retail Grocers' Association of the State of Illinois, if you will not prosecute under this law, it is your own fault. The manufacturers of this State want to give a good product. All you have to do is to say to the manufacturer, 'We want a pure article, something that will comply with the food laws of Illinois, and we want you, upon each bill that you send us, to make the statement, that these goods were manufactured in conformity with the food law of Illinois.'" And that pretty generally has been required, so that to-day, I don't care whether it is baking powder, I don't care whether it is maple syrup, or what the article is, we don't have very much trouble now.

I said to them, "If you do this, gentlemen; if you see that that is done, and then it proves to be an impure article, we will then prosecute the manufacturers and not the retailers."

What was the result? I will give you a little inside history of it, the secret history on the quiet—don't want you to say anything about it to those baking-powder people or any of them, how we managed it. In the first place, the first people who objected to this were the Royal Baking Powder people; they said, "We have been manufacturing Royal Baking Powder 28 or 30 years; now to compel us to change, the label will be equal to saying to the public, our goods are not as pure goods as we have been telling them all the time." I went to work with Dr. McMurty, the analyst for the company, and showed him wherein it was to their interest. I told him, "We feel confident the Royal Baking Powder is one of the best preparations;" and I also said, "You sell for 30 or 40 cents a can; and the powders with alum in sell for 25 and 30 cents. This is to your interest; the others who have been manufacturing cheap powders have been palming it off on the buyer. This ruling that every article should be stamped or labeled according to what it really contains, as for instance, baking powder, is in the interest of the best article. If yours is the best article, you want to uphold the hands of the commission." He went away, said he did not know about it; he would go back and report.

In about 5 or 6 weeks he came back—or, rather, he sent Mr. Boyesen, an attorney here in Chicago, to us and he came in with a letter from Dr. McMurty, stating that they had accepted our ruling, and they wanted to uphold the commission and they wanted us to make every other company label and carry out the law as our ruling required. I wondered why it was they had changed their ideas, and I asked Mr. Boyesen, and he said, "The fact is, we tried to sell it without that on the label, and the retailers would not buy it."

Now, wherever we have the retailers back of us, there is no trouble at all in this State. I want to say to you, we have the retailers of the State back of us, and we have had so far with all of these companies no trouble. You see what it led to. Here in Illinois they come to us—the larger cities, and especially in Chicago—saying, "Here, you are ruining our trade. We have had a good trade in syrups and honey and all that; we have been able, by making these 'blinds' or mixtures to sell, to compete; if we don't do it, we can't compete with these cheap fellows." We said to them, when they came to the office, "The cheaper fellows have to get out of the road; we are going to have nothing but the pure article; when it comes to maple syrup, it has to be maple syrup, nothing else goes on the label; and when we find any manufacturer that is making maple syrup that is not pure, we will prosecute him for it. That has not been the ruling. If they want to manufacture maple syrup and put anything in, let them label it partly glucose, and then it will be all right. It is the same way in regard to honey or to any food product, and when the consumer wants to purchase, he knows what he is doing. He knows what he is getting and he pays for what he gets.

For instance, you take maple syrup; it is worth about \$1.40 a gallon; glucose is worth from 40 to 50 cents, and so on all along the line, and by compelling them to label it just what it is, it gives the maple syrup manufacturer a show, whereas heretofore he has had none, and they have pretty nearly denied the maple syrup manufacturer out of the market; but from this time on, he is going to have his inning."

As I said, we want to uphold the very best article; that is one reason why this law was instituted, so that the consumer may know exactly what he is getting, and pay for what he gets.

Excuse me, your secretary, Dr. Mason, notified me that we were limited to five minutes. If I exceed the time, you will "call me down;" but I heard him say this evening what a nice, noble band this was. What was it he said? He had not heard a profane word, had not seen any one smoke nor chew tobacco, nor take a drink. Well, now, I can understand that. If there is anything that ought to lift one above the plane of all these common, grovelling things of earth, it is pure honey; it is the cause that you are engaged in, and others seeing your good works in these lower walks of life—the glucose fellows and so forth—will, after awhile, get some inspiration and quit their business and go into it right, like you are doing, and sail under proper colors.

This Commission, in all seriousness, this Pure-Food Commission is to let the people know just exactly what they are getting, and when we do that there is no mistake, and we are helping you out. You are the bee-keepers' association; whenever the glucose, the maple syrups, or other products that come in competition with yours—whenever they are compelled to label their goods just what they are, then the honey man has his innings, and he has a fair show, and that is the exact object, as I understand it, this Commission is trying to attain.

In conclusion, I want to say to you that we have a very fine laboratory; we are located at 1623 Manhattan Building; Dr. Eaton, our State Analyst, has charge of it, and you are invited, one and all, to come and look in upon us. We have said to all the other retail associations and manufacturers of the State of Illinois, whenever you find any one coming in competition with your business, that is manufacturing any product that is not what it represents itself to be, you notify this commission. We will send an inspector and inspect them, and then we will do the next thing—we will bring the strong arm of the law to bear upon them. Whenever we find from any reputable citizen that any one is violating the law by selling or manufacturing any article for other than what it really is, and palming it off for something that is inferior, all you have to do is to report that, and we will at once send an inspector, and we will seize the fellow and bring him up to the captain's desk, and there make him pay tribute to Caesar. [Applause]. So that if any one in your town, and you know it—if you live in Illinois—is violating this law, is running his business contrary to it, it is your fault if he does it; for we stand here ready, and willing, and *anxious*, for it is our duty, and we are paid for it, to see that the law is enforced all over this State. If it can be done here in Illinois, it can be done in every other State in the Union.

Another thing I might say while on this subject. Last October I had the pleasure of meeting with the National Commissioners' Association of all the States here at the Palmer House, and there a committee on rules was appointed to try to get rules and regulations that would apply alike to all the States—rulings upon the law; and then another committee to formulate a law, so that each and every State might have the same law. Up to this time, each State has had its own law, and its own rulings, and it naturally has made a great deal of trouble, and I think in the next few months we can obviate a good deal of that. Of course the law can't be changed until the respective legislatures of the different States meet and pass new laws—a new law that may be suggested by this committee. We are trying to arrange so that every State can work in harmony, and when the producers of honey in one State produce honey, they know that the label that is put upon it will go into every State in the Union, as well as every other food product. We are trying to help out in the interest of pure food, and especially pure honey; for we all believe in that, even if the glucose man won't say a word against good honey. I want you to go ahead in the good work you are in, and whenever you see in Illinois a man that is imposing upon your rights, by making an inferior article, that does not come up to the law, if you will just report him, he will suddenly cease to do business, or else he will conform to the law.

A. H. JONES.

Dr. Mason—It might be a pleasure to the Honorable Commissioner to know that this Association has started something in the same line of which he has been speaking. We have to-day appointed a committee for the purpose of taking into consideration this very work of formulating and suggesting to the legislatures of the different States some way by which we all might work in accord under about the same kind of rulings. We are glad to learn that others are working in the same line.

Mr. Jones—It has been my pleasure in the past to be connected with one of the State Institutions—the State Normal for Eastern Illinois—formerly located at Charleston. We have here this evening one of the faculty; I have known him—I don't want to say for how many years, or some of the ladies here, as well as the gentlemen, might think he and I are getting old. I will say I have known him for 25 years, and he has a fine, delightful voice, and I don't know of any one who likes to listen to it better than I do. He is great on recitations, and I think this evening he will favor us with one of his choice recitations. Ladies and gentlemen, I have the pleasure of introducing to you Prof. Brownlee, of the Eastern Normal.

Prof. Brownlee—Ladies and Gentlemen:—Let me say, I think I should not have been here if I had thought on this warm evening I would have been called upon. I came to hear the honeyed eloquence of my friend on this occasion, and not to say anything myself. This is "the most unkindest cut of all," I think. He promises me I should have nothing to do, if I would come, but look at some beautiful pictures thrown upon a screen, and I suspect at that very moment he had in mind introducing me to the audience. However, I am willing, if I can entertain you a little. I am here this week attending a great soldiers' convention. One of the things that I am very proud of is that I was a soldier in the Great War. [Applause]. On the right side, too. I think both sides were honest, but one side only was right. I was on the right side, the side we are all on now, and so if you will permit me, I will choose a selection bearing upon that great struggle.

Prof. Brownlee then recited, "Why the Old Man Would Not Sell the Farm."

Pres. Root—I am sure we are greatly indebted to Prof. Brownlee and the representatives of the Pure-Food Commission of Illinois, for calling upon us and so pleasantly entertaining us this evening.

A vote of thanks was then unanimously extended to them.

Continued next week.)

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Richards, Ohio.

THREE KINDS OF HONEY IN ONE APIARY.

It looks business to see three kinds of honey reported from an apiary instead of two—Extracted 11,900 pounds; bulk comb 7,800 pounds; section honey, 1,404 pounds. And, O ye furiously and completely reformed brethren, what are you going to do about it? O. P. Hyde & Son, page 44.

BUMBLE-BEES IN WINTER.

If I understand Mr. S. T. Pettit rightly, he has found in winter some kinds of bumble-bees, not all the species. Well, that's a good beginning—in dry cavities drifted full of leaves under big, old logs. If I ever found any I just went and forgot about it. Still, I guess there's nothing mysterious in the case. A thousand species of insects we seldom see in winter nevertheless get thru somehow. Presumably brood-rearing ceases early in a bumble-bee's nest; the slender stock of stores gets eaten up; then each bee for herself says, "What is home without a baby"—and without any call to dinner? And thereupon she wanders abroad. I suppose these wanderers forage and bask in the sunshine when it is pleasant, and hibernate the warmest place they can find to crawl into when night approaches—not to come out for a week unless weather is fine—and eventually weather-bound until spring, providing they don't get water-soaked and frozen up beyond restoration before that time. Page 44.

CREDIT TO WHOM CREDIT IS DUE.

"Dees do nothing invariably." A good editorial on that topic is the one on page 51. But I shouldn't have told you so were it not that Sonny in the Progressive Bee-Keeper credits the proverb to me. Give Mrs. Tupper her due.

DOOLITTLE AS A "GREEN BEGINNER."

G. M. Doolittle as the "Arkansas Traveler," and by and by, may be, the Arkansas resident, why, we wouldn't know him! "Who's that green beginner off there?" we'd be saying. Page 52.

THE "BARRELS VS. CANS" CONTROVERSY.

In the long discussion of barrels versus cans on pages 53, 54 and 55, several things are apparent. One is that that heavy villain, the barrel, is not about to pull a tombstone over his head right away. Another thing is, that those who succeed well with barrels from year to year take more care than average humanity will take until pretty sorely whipt with losses and annoyances. Another thing is that the whim of a big buyer who is used to getting his honey in barrels has got to be yielded to. He'll buy of somebody else if you don't yield. Perhaps most remarkable of all is the utter decadence of the practice of treating barrels with wax or paraffine. Not one waxes his barrels now; and most, in their talk, seem not to have any such practice in their minds. Yet awhile ago we were to wax the barrels, of course, if we went according to book. Why is this thus? I'll venture the guess that waxing does no harm, but that it encourages the neglect of other precautions which are worth more. Or is it that ordinary, hard-wood barrels will leak in spite of it, while just the right kind of soft-wood barrels can be made to refrain from leaking without it?

EARLY QUEEN-REARING.

And as advice ament getting wedded to early queen-rearing Mr. Doolittle pronounces the traditional "don't." D'y'e hear, ye callow young people? And if you *will* disobey (young people have been known to do so) you *must* wait longer than merely to see young drones in open cells—else your queens will have to wait. Queens started when plenty of drones have been sealed a week—is the correct matter.

Quite interesting is Mr. Doolittle's observation that the queen's development may be hastened at the utmost only one day, while it may be *delayed* four days by unpropitious circumstances and weather in the fall. Page 55.

"POP" AND HIS BEE-BOAT.

Mr. Poppleton and the "Thelma," on page 58, make me feel envious and piratical, c'enymost. Doubtful if anybody has ever found a better way to combine the three—health-seeking, pleasure and moderate profit—than by this open-air life of cruising and "beeing" along the coast of Florida. As we look at him standing there in the sunlight we are just prepared to hear him say (albeit he is gray-bearded and somewhat bent), "Wouldn't call the President my brother this minute." Six miles per hour will get there sufficiently soon if the "there" is not too far away. None of our business, but we are regretful that he did not give us the total cost of the little steamer.

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can add much by sending in the names and addresses when writing us on other matters.

The American Fruit and Vegetable Journal is just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both for \$1.00.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Flat-Bottom Queen-Cells.

I have made a lot of artificial queen-cells, *a la* Doolittle, with flat bottoms. Since making them I have been informed that the bees will not accept them as readily as the round-bottom queen-cells. Which is the better?

COLORADO.

ANSWER.—I never before heard of queen-cells with flat bottoms, and I don't believe the bees would like them. Still, you can hardly be sure about anything without having the bees try it, and it is possible the bees might accept queen-cells with flat bottoms.

Amount of Honey in 10 Frames Spacing Frames.

1. How many pounds of apt honey is there in 10 Hoffman frames (9 inch) before it is extracted?
2. If I choose to space them 8 frames in a hive, how far apart can they be put?
3. Is there any danger of the bees building combs on the cover?

CALIFORNIA.

ANSWERS.—1. I don't know what you mean by "9 inch," unless it be the depth of the frame, the usual depth of the Hoffman frame being 9½ inches. Ten Hoffman frames well filled may contain as much as 60 pounds of honey, if there is no pollen in them.

2. That depends upon the width of the hive; but you probably have reference to having 8 frames in a 10-frame chamber. In that case you would space the frames about 1¼ inches from center to center.

3. If you put 8 frames in a 10-frame chamber, and the cover is only ¼ inch above the top-bars, as is generally the case, there will be no danger, I think, that the bees will do much more at building comb above than with the 10 frames.

Hives Damp and Moldy in the Cellar.

My nine colonies of bees are wintering in the cellar. They are in 8-frame dovetailed hives. The cellar is moderately dry and warm—vegetables keep well in it. The hives were brought in from the summer stands Nov. 20th, the bottom-boards removed, and the hives placed crosswise upon a shelf some two feet from the ground. This shelf is about a foot wide, so the middle of the hive rests upon it, leaving a space three inches or more open at each end of the bottom of the hive for ventilation. The hive-covers have remained sealed down as on the summer stands.

I noticed, Jan. 30th, on raising a hive-cover, that it was wet beneath, so much so that water dript from it, and some mold appeared on the top of the frames. The colony, to all appearance, was strong and vigorous. I should judge all the other colonies are in the same condition as this one examined. What would you advise me to do with them?

MAINE.

ANSWER.—Your bees may come out all right if you let them entirely alone. But it is certainly no benefit to them to have water standing on the cover, and if that water drips on the bees it may be a damage. The moisture from the bees comes in contact with the hive-cover, and the hive-cover is so cold that the moisture condenses upon it just as water from the air settles on a pitcher of very cold water on a hot summer day. If the cover were warmer, the moisture would not be so much inclined to settle upon it. Possibly the cellar should be warmer. Try it by a thermometer, and try to keep it somewhere in the neighborhood of 45 degrees, or, to be more exact, keep it at the temperature at which the bees are most quiet. If the air of the hive had freer escape, the moisture would escape with it. To help in that direction it may be a good plan to raise each cover and put a common nail under it, so as to make a small crack for the air to escape.

GENERAL ITEMS

A Beginner's Report.

I have been keeping bees for over two years. I bought 5 colonies at \$7.50 each, in Langstroth hives. I took off 300 pounds the first season, and increased to 11 colonies. The next season I secured 500 pounds of extracted and 200 pounds of comb, and increased to 21 colonies. In the fall I sold the 21 colonies at \$5.00 each, and went out of the business, because I could not stay at home to care for them properly, but I still take the Bee Journal, and enjoy reading it. I think I did well for a beginner.

J. A. Moss.
Missoula Co., Mont., Jan. 24.

Honey-Failures a Matter of Locality

I have read in the Bee Journal of the hard times bee-keepers have had in Southern California in consequence of the rather dry seasons, and fear that others may get the impression that there were general failures of the honey crop all over Southern California. I would like to say in justice to this part of the country, that the failures were more a matter of locality. It is quite true that the last three years we have not had the average rainfall, but in spite of that, in well adapted localities, there is always some honey secured.

For instance, last season I secured over 5,000 pounds of surplus honey from 36 colonies, which is about 140 pounds per colony, and increased to over 80 colonies. Most of the bee-keepers in this vicinity and the neighboring valleys got as much, and some even more. Mr. J. M. Hambaugh secured 150 cases of extracted honey, each containing 120 pounds net, which is about 200 pounds per colony. These are not bad results for a dry year, and show what we may expect in a good season. One of our country stores ship two car-loads of honey to Germany the past season, and two more car-loads were consigned to the East.

Since Christmas bees have been collecting nectar and pollen from manzanita, eucalyptus, pepper-trees, wild gooseberries, currants, California lilacs,

Cuba.
by The American Tramp

This writer has been in Cuba some two years, and writes understandingly.

SPECIAL OFFER.—Each one of the issues mentioned above should be worth a dime to every bee-keeper, but we will send all three for only 10 cents. Hurry along your order before they are all gone.

BETTER YET. Send us 25 cents at once, and we will send you Gleanings in Bee-Culture 12 issues, 6 months, beginning Jan. 1st. Feb. 15th will contain several articles on

Cuba,
by Harry Howe, Robert Luaces,
and A. L. Boyden

Mr. Howe was formerly with Coggshall, of New York, and has already given Gleanings readers glimpses of Cuban bee-keeping. Mr. Luaces, of Puerto Principe, considers that conditions are not well known, and gives information somewhat different from other writers. Mr. Boyden begins a series of articles, entitled, "Glimpses of Cuba and Cuban Bee-Keeping," illustrated by photos taken by himself.

Remember. Six months for 25 cents, and your money refunded July 1st if you are not satisfied. Mention the American Bee Journal.

THE A. I. ROOT COMPANY, Medina, Ohio.

SEND 10 CENTS

To receive postage and packing and receive this valuable collection of seeds postpaid, together with our new **Illustrative, Beautiful Seed and Plant Book**, tells all about the best varieties of seeds, plants, etc.

H. W. Buckbee Box 537 ROCKFORD, ILL.

etc. The orange trees will soon be in their full glory, and it is a sight to delight one's heart to see the bright-colored fruit between the dark green foliage, the trees covered with the fragrant blossoms, and innumerable humming bees collecting the sweet nectar. Almonds, peaches, apricots, and other fruit-trees will also soon be in bloom, besides alfalfa and numberless wild flowers.

Bees are building up very nicely to be ready for the main honey-flow from the far-famed black and white sage honey, which begins in April in good seasons, and lasts until about the middle of July. After this sunnuc, wild buckwheat, and other nectar-yielders continue till October.

We have had three nice rains this season, and it begins to look as if the more favorable conditions were returning again.

L. MARNO.
San Diego Co., Calif., Jan. 24.

Bees Did Poorly.

The bees did poorly in this locality the past season. I did not get any swarms, and hardly secured honey enough for winter stores.

This is my second year of bee-keeping, and I have five colonies now which I transferred into new hives.

D. E. EVERS.

Otoe Co., Nebr., Jan. 29.

Prospects Good for the Coming Season.

The past season was a bad one for the apiaries in this State. Most of them are left in a mix-up condition; many are diseased, nearly all are reduced in number of colonies, and there must be many that have been wiped out of existence.

From my 100 colonies, spring count. I increased to over 130, extracted 6,000 pounds of very fine sage and buckwheat honey, and rendered over 100 pounds of wax. I have sold but little of the honey, and I shall make the wax into foundation.

The prospects for the coming season are much more favorable than they have been for three years, and if the conditions continue there will be a rich harvest for the bees. Yesterday I went to my out-apiary, some 25 miles from the city, to "size up" the situation as to the prospects, and came away in good spirits, altho I got a good soaking before returning. Last year we had 4.57. 100 inches of rain; this year to date we have had 9 inches, and it all

Four Celluloid Queen-Buttons Free

AS A PREMIUM

For sending us ONE NEW SUBSCRIBER
to the American Bee Journal for three months
with 30 cents, we will mail you FOUR of these
pretty buttons for wearing on the coat-lapel.
(You can wear one and give the others to the
children.) The queen has a golden tinge.

This offer is made only to our present regular subscribers.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good
idea for every bee-keeper to wear one [of the buttons] as it will cause people to ask questions
about the busy bee, and many a conversation thus started would wind up with the sale of
more or less honey; at any rate, it would give the bee-keeper a superior opportunity to en-
lighten many a person in regard to honey and bees."

Prices of Buttons alone, postpaid: One button, 8 cts.; 2 buttons, 6 cts.
each; 5 or more, 5 cts. each. (Stamps taken.) Address,
GEORGE W. YORK & CO., 118 Michigan St., CHICAGO.

HAMMOND'S

Michigan Northern-Grown Onion Seed.

1 sold 56,000 lbs. of this seed in 1899. My
customers report yields of 450 to 1,250
bushels of onions per acre from this
seed. Some of them intimate that this
seed is worth \$5 to \$10 per lb. more
than the California grown seed sold by
anybody. I guarantee this seed to be
new and healthy grown. We have seed
of all the leading and standard vari-
eties. We make special prices on large
lots. Onion sets of all varieties. Buy
direct from the grower. Catalogue
extended and illustrated free.

under a fall apple-tree which bore apples about the color of lemons, and two under a winter apple-tree, the apples having a brownish color (rusty coats), and the worms from these trees dropt on the hives underneath them, and workt their way into the hives and around the sides, and in each instance the worms were the color of the apples in the tree above the hive on which they fell.

It is my opinion that the worms that fall from the trees and crawl into the hives are the color of the tree from which they came until they become millers.

The worms which got into the colony under the grape-vines were of a natural color.

I went into the country to visit a friend, and while I was there he made apple-cider, and askt me to help him, which I did. We went to the orchard and gathered the very best of the apples, cutting out the cores and all the rotten and worm-eaten spots. After throwing the cores away I noticed hundreds of millers gathering on them, then I lookt up and saw as many among the trees, and some of them alighted on the apples. The next morning I examined the apples, and found that the millers were stinging them, and planting their eggs in those that were ripe or matured. The millers sting the apples at the stem, at the blossom end, and on all sides, and when the eggs are hatcht into worms they work themselves toward the heart of the apple.

I would like to know if it does any good to spray the trees while they are in blossom. Some of our professors claim that the eggs that are laid in the blossoms are killed when the trees are sprayed. I do not believe it does any good to spray the trees, as my observation is that the millers plant their eggs in the apples after they have matured.

AUGUST ROSENBERGER.
Iroquois Co., Ill., Dec. 10, 1900.

[See the article on spraying fruit, on page 120 of this number.—EDITOR.]

Convention Notice.

California.—The annual convention of the California State Bee-Keepers' Association, will be held in the Chamber of Commerce, at Los Angeles, Feb. 25 and 26, 1901, beginning at 1:30 p.m., on the 25th. Several valuable papers have been promised, and we expect an interesting convention.

CAREER AND CHARACTER OF ABRAHAM LINCOLN.

An address by Joseph Choate, Ambassador to Great Britain, on the career and character of Abraham Lincoln—his early life—his struggles with the world—his character as developed in the later years of his life and his administration, which placed his name so high on the world's roll of honor and fame, has been published by the Chicago, Milwaukee & St. Paul Railway, and may be had by sending six (6) cents in postage to F. A. Miller, General Passenger Agent, Chicago, Ill. 6A3t

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Jan. 19.—Honey is selling slowly; this applies to all grades with the exception of white clover and basswood comb honey, which sells readily at the providing it grades No. 1 or better. All other kinds of white comb honey sell at from 13@15c; and canned white comb at from 8@10c; travel-stained and off-grades of comb, 13@14c; amber, 12@13c; amber extracted, 7@7½c; dark and buckwheat comb honey, 9@10c; Extracted, white, 12@13c; basswood and white clover bringing the outside prices; buckwheat and other dark grades, 6@6½c. Beeswax, 26c. R. A. BURNETT & Co.

KANSAS CITY, Jan. 22.—Fancy white comb, 15@17c; amber, 13@14c; dark, 9@11c; demand good. Extracted, 7@9c; demand quiet. Beeswax, 26@30c.

W. R. CROMWELL PRODUCE CO., Successors to C. C. Clemons & Co.

CINCINNATI, Feb. 9.—The market for comb honey is becoming very bare, although the prices have not changed. Fancy white comb is still selling for 16c; no demand for darker grades. Extracted is in fair demand; dark, 12@14c; for 5½c; better grades from 6½@8c; only white clover brings from 5½@6c. Beeswax, 28c. C. H. W. WEBER.

ALBANY, N. Y., Feb. 11.—Honey market is dull and prices nominal; light stock, but the cold weather is bad for it. Comb, in good order, not candied, white, 15@16c; mixt, 12@14c; dark and buckwheat, 11@12c. Extracted, white, 7@8c; mixt, 6@6½c; dark, 5@6c. H. R. WRIGHT.

BUFFALO, Feb. 8.—Some more active this week, and mixt clean up better than expected awhile ago. Fancy 1-pound comb, 15@16c; No. 1, 14@15c; No. 2, 12@13c; dark, buckwheat, etc., 8@10c. Beeswax, 25@28c. BATTERSON & Co.

BOSTON, Feb. 8.—Fancy No. 1 white in cartons, 17c; A No. 1, 16c; No. 1, 15@16c, with a fairly good demand. Absolutely no call for darker honey; this year. Extracted, white, 8@8½c; light amber, 7½@8c. Beeswax, 27c. BLAKE, SCOTT & LEE.

NEW YORK, Dec. 22.—Fancy white, 15@16c; No. 1 white, 14c; No. 2 white, 12@13c; amber, 12c; buckwheat, 10@11c. Extracted in fairly good demand at 7½@8c for white, and 7c for amber; off-grades and Southern in barrels at from 65@75c per gallon, according to quality. Not much demand for extracted buckwheat as yet. Some little selling at 5½@6c. Beeswax firm at 28 cents.

Demand continues good for comb honey; supply fairly good. Extracted in fair demand with enough supply to meet requirements.

HILDRETH & SEGELEN.

DETROIT, Jan. 19.—Fancy white comb, 15@16c; No. 1, 13@14c; dark and amber, 12@13c. Extracted, white, 7@7½c; amber and dark, 6@6½c. Beeswax, 26@27c. M. H. HUNT & SON.

SAN FRANCISCO, Jan. 9.—White comb 13@14 cents; amber, 11½@12½c; dark, 8@9c. Extracted, white, 5@5½c; light amber 6½@7½c; amber, 5½@6½c. Beeswax, 26@28c.

Stocks of all descriptions are light, and values are being as a rule well maintained at the quoted prices. In quality, quality, and lowest pronounced on light amber and water white honey, the latter being in very scanty supply.

HONEY MARKET.—We may have a customer within a short distance of you who wants your honey or beeswax. We are in close touch with all the markets; therefore write us regarding your crop, stating quantity, quality, and lowest cash price. References—Either Bank here for any business man in this city.

Des Moines Incubator Co.—It was a happy thought years ago that suggested the name "Successful" to the Des Moines Incubator Co. for their standard machine—a name fully deserved by its record. With commendable enterprise necessary additions have been made to their factory from time to time, and to further facilitate the handling of their immense business, they have now added a large storage warehouse. It is located directly upon railroad tracks, so that carload shipments can be made with ease and promptness. An illustration of their warehouse shows one loaded for O. Rolland, Montreal, agent for the Des Moines incubators in Canada. Another car is a partial shipment to F. Lassetter & Co., of Sydney, Australia, who are handling the Des Moines machines in large quantities this season. This is only one instance of the large foreign trade the Des Moines people have built up, and which has necessitated their printing catalogs in 5 foreign languages. We believe they are the only incubator manufacturers who have had to do this. Space will not permit any extended description of their machines, but their large and constantly increasing business is the best endorsement they could have. The "Successful" is their leading machine, but the "Eclipse" and "Crescent" are thoroughly dependable, and are most excellent value at the price asked.

Careful readers may remember very remarkable hatches made by the Des Moines Company at several large poultry shows last year, incubation being started at Des Moines and timed to bring out the hatches during the exhibits. While being incubated the machines with their precious contents were shipped almost 1,500 miles by express, were several times transferred in open wagons, and all without diminishing the high percentage of chicks hatch, for which the Des Moines machines are famous. No other explanation of these remarkable feats can be given other than the great care taken in the building of these incubators, and the correct and scientific principles upon which they are made.

Readers of this paper who contemplate purchasing an incubator, will certainly serve their interests by sending for the Company's new catalog. Please refer to their advertisement elsewhere in this paper, and note the conditions under which the book is sent. It cost the Company a great deal of money to compile it, and it should on that account find a permanent place in every poultry breeder's library. Address, Des Moines Incubator Company, Des Moines, Iowa, and kindly mention this paper when writing to them.

AMERICAN

BEE JOURNAL

The Bee-Keeper's Guide:

Or. Manual of the Apiary.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousandth—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without *THE BEE-KEEPER'S GUIDE*. This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we will give it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

Long-Tongued Bees

ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2; or, one Tested Queen free as a premium for sending us FOUR new subscribers (with \$4.00.)

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation—"first come, first served"—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO

144 & 146 Erie St., CHICAGO, ILL.

26 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 26 cents a pound—CASH—for best yield, upon its receipt, or 28 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO.

Best White Alfalfa or Basswood Extracted Honey

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are box.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

* Editorial. *

Joining the National in a Body.

Several local associations have already taken advantage of the provision in the constitution of the National Bee-Keepers' Association, which reads as follows:

"Whenever a local bee-keepers' association shall decide to unite with this Association as a body, it will be received upon payment by the local secretary of 50 cents per member per annum, provided that the local association's membership dues are at least \$1.00."

Referring to this matter in a recent letter to this office, Dr. A. B. Mason said:

EDITOR YORK:—I have just forwarded a draft to General Manager Secor for the amount of fees required to make the members of the Cayuga Co., N. Y., Bee-Keepers' Society members of our National Bee-Keepers' Association. Also, I have just received a letter from the Worcester Co., Mass., Bee-Keepers' Society, making enquiry as to the terms on which their organization of 40 members can join the National.

Won't you just suggest that all the local bee-keepers' societies on this continent "go and do likewise?" Also add that it is necessary to send the name and post-office address of each member with the membership fee.

A. B. MASON.

LATER.—I have just received a letter from General Manager Secor, saying: "New members are coming in all the time, and the finances are in a healthy condition." That's the kind of a "ring" to have, and to hear, and to belong to.

A. B. M.

We are indeed glad to learn of more bee-keepers' societies taking advantage of the low membership fee when joining the National in a body. We believe the Wisconsin State Bee-Keepers' Association was the first thus to join, and was followed by the Chicago Bee-Keepers' Association a month or two later. At the recent meeting of the Wisconsin Association the memberships were renewed for both the State and the National associations. This is just as it should be.

The fact that more organizations are "enquiring the way" is a healthy sign, and should ultimately increase very largely both the membership and the treasury of the National. It will be surprising to all, what can be done in many ways when bee-keepers once unite, not only to defend themselves, but to push their interests on every occasion when to do so is both proper and right.

We have been greatly encouraged during the past month or two on account of receiving so many membership fees at this office, all of which have been duly forwarded to General Manager Secor, who doubtless has promptly mailed individual membership receipts. We

are ready and willing at all times to receive such dues and send them to Mr. Secor.

We wish there might be more local societies organized under the provision of the National constitution, as before quoted, and that all such local organizations might see their way clear to elect say two delegates to the National convention each year. This would not only be an honor conferred upon those delegates, but would furnish the kind of representation in the National that every local association should have. Suppose there were 50 local associations scattered over the United States and Canada, each one of which should send two of their best men to represent them in the National Association. If the representatives would attend the National there would be an assured attendance of 100 of the best bee-keepers in all the country. This of itself would insure a great convention, to say nothing of the attendance of bee-keepers residing within 100 or 200 miles of the place of holding the National convention. Of course, there should be more than 50 local societies in the United States alone.

What we would like to see is this: Let there be county and district associations holding an annual meeting, and sending one or two delegates each to the annual State convention; and each State association send two delegates to the National. This would give representation to the humblest members of the pursuit. Membership dues of \$1.00 in the county or district association should be sufficient to make each bee-keeper a member of all three organizations. Twenty-five cents of the \$1.00 can be retained by the local association; 25 cents to be sent to the State organization; and 50 cents to the National, just as is provided for now.

We fully believe this scheme is entirely workable, and that some arrangement ought to be made at the next National convention providing for this plan or something similar. We are ready to co-operate along any line that will give promise of unifying the bee-keepers, and building up an organization that will be able to take care of their interests.

The Anti-Bee-Legislation, as recently proposed in the Wisconsin Legislature, has received its deserved quietus. Mr. N. E. France, president of the State Bee-Keepers' Association, wrote us as follows about the matter, Feb. 9th:

"This morning the Legislative Agricultural Committee at Madison, reported for *undebated postponement*, on Bill 132A, to assess and tax bees, also to license moving bees to any other town than owner's residence."

Mr. France has been working almost night and day since the State Bee-keepers' meeting, Feb. 5th and 6th, to accomplish the above

action. We knew he would be successful, for there was rank injustice in the bill referred to. For instance, the great poultry industry of Wisconsin is not taxed. Why, then, tax bees, which are so much more uncertain stock than is poultry? Personally, we think bees should be taxed at a small value per colony, but not before poultry is put on the property list.

Again, the bill proposed to tax those bee-keepers who desired to practice migratory bee-keeping. It provided that any bee-keeper who desired to move his apiary to another field where the bees might take advantage of a better honey-flow, must pay a license fee of \$1.00 per colony per month before being allowed to move into another township. That is, if he had 100 colonies which he wished to move to another field for four months, he would have to pay a license fee of \$400!

No sane legislators would favor such injustice, we are very certain.

The Apiary of Mr. F. M. Wagner is shown in two views on page 135. No. 1 presents it with the revolving roof in a horizontal position to shade the hives from the noontday sun. No. 2 shows the roof on a slant to protect from the afternoon summer sun, or from chilling winter blasts.

In a letter accompanying the photographs, Mr. Wagner says:

The hives are the 10-frame, with an all-wood blanket between the brood-chamber and the super, but held up from the frames so the bees can pass over from frame to frame. The super is then filled lightly with short straw. The ventilation seems to be enough for this climate [Adams Co., Ill.], under a trial of four winters, south of the 40th parallel, and three miles east of the Mississippi River.

Value of Bees to Alsike Clover. Secretary Conso, of the Ontario Bee-Keepers' Association, said at the last convention that the nearer a field of Alsike clover is to an apiary the better the yield of clover seed. He had applications from two men who wished him to locate bees near them. The value of bees to fruit-growers and farmers is being proven over and over as time goes on. Ignorance is a hard thing to overcome, but it's yielding more and more.

Tin Cans vs. Barrels. Mr. J. H. Martin, in *Gleanings in Bee-Culture*, offers another argument in favor of tin cans for shipping honey. He says: "Freight rates on honey in tin cans cased, from California to the East, are \$1.10 per 100 pounds; on honey in barrels, \$1.20 per 100 pounds; on honey in glass, \$1.20 per 100 pounds. Observe honey in barrels and glass is in the same class. The railroad companies evidently know where the greatest risks are."

Comment is unnecessary.

Weekly Budget

Prof. A. J. Cook writes us that the "bull dog ant" of Florida, mentioned on page 72, is "*Camponotus esuriens*, Smith," which he learned from Dr. L. O. Howard, entomologist of the Department of Agriculture, Washington, D. C.

THE OFFICERS of the Ontario Co., N. Y., Bee-Keepers' Association is as follows: President, W. F. Marks; vice-presidents, H. L. Case, John Page, Chester Olmstead; secretary, F. Greiner, of Naples; treasurer, L. B. Smith; and honey inspector, E. H. Perry.

MRS. ARTIE BOWEN, of Merced Co., Calif., writing us Feb. 12th, said:

"I think this is going to be a good honey-year in California. The bees in this locality have wintered well so far, and our winter is about over. The almonds are coming into bloom, and within two weeks our orchards will be in full bloom."

MR. W. E. FLOWER, of Montgomery Co., Pa., is one of the noted bee-cranks around Philadelphia. He it was who gave a short illustrated talk on bees when the National convention met there in 1899. It was enjoyed by all. We understand that he expects to give another talk on the same subject at Franklin Institute very soon. There will be a male quartette to sing "The Hum of the Bees in the Apple-Tree Bloom," accompanied

by piano, cornet, and two violins. They are good players and singers, as they all belong to the church choir of which Mr. Flower is a member, and they will doubtless make things hum. Mr. Flower expects to have a lot of new slides to show, and very likely some new jokes and stories to help entertain his audience. Mr. Flower knows how to do it, and will be able to give a good entertainment.

MR. L. HIGBARGER, of Ogle Co., Ill., writes us that during the meeting of the National convention in Chicago last August, he suffered a stroke of paralysis so that he had to leave for his home before the close of the meeting. It left his nervous system in bad condition, especially affecting his eyes, so that it is very difficult for him either to read or write. He was 73 years old last New Year's day. All will unite in hoping that he may soon recover. He reports his bees as wintering well.

REV. A. B. METTLER, of Will Co., Ill., whose questions were answered on page 99, writes us that the only birthday he ever had was Feb. 1, 1844, and that all the February 1st's since that time have been *anniversaries*. That's very good. We will forgive him for the joke, seeing he sent his dollar membership fee for the National Bee-Keepers' Association.

BISHOP WM. A. BILES, of Salt Lake Co., Utah, wrote us Feb. 15th that bees were a failure in Salt Lake county last year, tho in previous years he had over 350 pounds of honey per colony. He sent us two clippings about bee-keeping in Uintah Co., Utah, men-

tioning one firm of bee-keepers who had 160 colonies of golden Italian bees that averaged 331 1/4 pounds per colony last season. Ashley Valley, in which is located this bee-keepers' paradise, is about 20 miles long by 6 wide. Vernal, the county seat, is a busy little city, and is centrally located in this valley. It is a progressive town, with neatly-graded streets, paved sidewalks, and well-equipped business-houses. In the matter of taxes it stands as a model. It has never levied what is known as a town tax, and is absolutely free from debt, with a balance in the treasury. Very likely they are not crust with saloons.

Bee-keeping seems to be a new industry in Ashley Valley, but it is making astonishing strides, and one that promises to forge still further ahead in this sterile desert section. The honey-source is principally alfalfa, and the grade produced is of the best. Aside from the local consumption, 340,000 pounds were shipped last season, netting the producers 5 cents per pound. The success which has followed the efforts of bee-keepers in that part of the State is encouraging them to equip their apiaries with the latest appliances, which shows an intelligent grasp of the business. It is a little less than marvelous that so much real sweetness should be found in what was once such a desert-like and forbidding region.

MR. G. GLEYSTEN, of Sioux Co., Iowa, wrote us as follows Feb. 14th:

"The American Bee Journal is a welcome visitor each week. I could not get along without it. By the way, the wood binder is just the thing. Every subscriber should have one so he can flip away the journals each week, and always have them all together, ready for any reference he might want."

Convention Proceedings.

Report of the Proceedings of the 31st Annual Convention of the National Bee-Keepers' Association, held at Chicago, Ill., Aug. 28, 29 and 30, 1900.

BY DR. A. B. MASON, SEC.

(Continued from page 122.)

Pres. Root—We will now listen to Mr. R. C. Aikin, on the subject of

CO-OPERATIVE ORGANIZATION AMONG BEE-KEEPERS.

To organize is proper, right, and just. Like all else, organized combinations may be powerful for good or evil, according to the inclinations and desires of the organized. Condemn not organization, only its improper use.

Never in the history of the world have there been times of so great organization as at the present. Unions, associations, syndicates, trusts, etc., exist on every side. Were it not for organized business and social affairs, we never would have reached the heights of luxury, wealth, and power, now enjoyed by the present age. Even the anarchist organizes to break down governmental order. We organize for mutual help in all lines of business, industries, education, religion, and government.

But for what shall the bee-keepers combine? This, our national association, is largely social and scientific, with a little business mixt in now and then, and a mutual protection against unjust financial and moral enemies. So far this is good, but it does not cover, by a long way, the ground

it should to help the people where they need it most, in properly distributing our product.

These are days of specialism as well as organization and co-operation. More and more do we become dependent upon one another in all our affairs, as we grow in organized work. How long would our government, the postal system, railroads, churches, schools, and the very many great organizations, stand, if it were not for the co-operation features of those concerned? It is plain common-sense that in these days when specialism is everywhere prevalent, in almost everything, that those who produce our food—wheat, corn, potatoes, butter, eggs, meat, fruits, etc.—there should be co-operation.

But what is the great need of the bee-keeper to-day—in what particular direction should he co-operate to obtain best results? Is it on the social side? Surely not. We have social facilities in our organizations here and there, and in our class journals. The crying need of to-day is business co-operation.

Producers bring their wheat and other grain to the elevator; cattle, hogs and sheep to the stock-yards; and fruits to the fruit depot. In every producing locality, the products of that territory find buyers and places to deliver and store the products—facilities for handling. Just take one good look at the facilities everywhere established for the accommodation of the principal products, note that if I produce ten bushels of wheat and my neighbor his hundreds or thousands, there is one common price and I can take my ten bushels and sell it and have my check just as quickly and surely as the large producer on hundreds.

Now turn your gaze upon our apicultural products—can you go to town, *any* and *every* town, and *any* day, and there sell your products? You may sell a few pounds or cases to your local dealer, just what he needs for immediate retail. Should you produce more than the half dozen cases or so your grocer wants, and want to get cash out of it, what will you do? Well, ship it to some city market such as Denver, Kansas City, Omaha, Chicago, or other practical market; "consign" it to somebody you do not know, *take all the chances* yourself, get your money when you can in the

"sweet by-and-by," or order honey pushed onto the market, which means to give it away. Looks gloomy, doesn't it?

Honey-producers are so scattered, the product so limited in a given locality, that there is no inducement to put in proper facilities for the handling of the goods. Comb honey is somewhat regular and has a reasonable standing, but extracted, as handled by most producers, must not get out of sight of the producer until it is eaten, for you know he must "take it back and liquefy it." While almost every other product can be sold at any and all times, and for spot cash, honey must beg to be taken in dribs!

Tell me, if sugar would go liquid in the grocery, must the manufacturers take it back and regranulate? Is there any other product aside from extracted honey that must remain under the oversight of the producer or manufacturer until consumed? Answer me that, and you may have a little consideration for the custom of "taking back" honey to liquefy. If we must liquefy, then good-by to the industry as a settled business, or extracted honey as a staple. But I am slightly digressing.

Since it is so that the honey product is scattered, produced by littles here and there, it comes that there is no ready market for it locally. True, each producer sells more or less about home; but the trouble is, we who are poor and must realize on our product, and do it quickly, can not wait months to deal out in little dribs a small crop of honey. Those who produce by the littles—a few hundred pounds of honey, a few acres of corn, of apples, wheat, and of such a few bushels; a half dozen hogs, one or two beesves, etc.—such are the masses, and are the people that must and will sell, and just as soon as possible after the product is available. These small producers are said to ruin prices, and the charge is true to a limited extent. But can we blame these people? and after all what can we do? They are at the mercy of the more opulent buyer, or they perhaps must realize, and that quickly, and since there may not be a demand for their product and it is too small to ship to distant points, they are practically compelled to force the market, and the stock sells for less than its real and true value, and so prices are not what they should be.

It is necessary, then, that provision be made whereby, especially the small producer, may have a market for his product. The large producer is told to buy up the little lots and so get them out of the way, but large producers have difficulties to face, too. It does not take many little lots to require several hundreds of dollars—even thousands—to buy them. The large producer has to face the fact that if he competes in the general markets, and with other large producers and shippers, he must produce and ship in carlots, and to do this causes him to reach out to the limit of his own capital and ability. Yes, even the large producers, too, are struggling to keep from being eaten up by the still larger fish.

In these days when our products are transported hundreds and thousands of miles to be distributed—in reality exchanged for other products which we have not in our own localities, but which we think we must have, and social conditions almost compel us to have—there must be facilities for carrying out the exchange economically.

Look again at the immensity of the systems of transportation of products. The packing companies have their special cars. Then there are the fruit-cars specially designed to transport fruits and deliver them successfully at distant points; and grain, sheep and cattle cars. Not only this, but everywhere distributed thruout the country are both the gathering and distributing facilities. The large cities have their commission-houses with a side honey department, but what of it? Small producers, 500 or 1,000 miles from these places, do not want to consign. They can not afford the local freights and other expenses. The 10 or 20 cases of comb honey of the small producer, mean more to him than do the hundreds of cases of the large producers and commission and other dealers to them. These small producers have honey to sell, and must sell.

What we want, then, most of all, is the facilities for gathering the product and relieving the poor small producer by paying him for his honey and wax. These facilities must reach out from some central place and come close enough to the little apiaries so that their product can be delivered to the buyer with the very minimum of railroad freights. That such system is very much needed is surely evident, but as yet the solution of the difficulty is not clear. Many difficulties lie in the way, yet none but can be overcome.

I shall not attempt to lay down set rules to govern in working out this question, it can come only by co-operation. I say by co-operation, but not by it pure and simple, accord-

ing to the general acceptance of the term. I think I know enough of human nature to know that this Association can not in open convention work out such problems and carry them to completion. We have ideas as to what we need, but how to obtain the results we do not know, each guessing at what is needed and advising, yet there will be such diversity of opinions that no tangible thing can be arrived at. Your humble servant has been thru the mill and knows a few of the difficulties to contend with, how a convention will wrangle, and suggest, and advise, and demand, etc., then in the end tell a committee to go ahead and bring order out of chaos, yet not a dollar for the expense of doing it.

Discussion in convention is all right, and appointing committees is all right, but committees need financial help. Select for the committees straight, honest men—men who are the most familiar with the business world and methods, who have the facilities to obtain information and results. Remember that we must do much as we can, not as we like. We want to put our product as near where it ought to be as possible, but in doing this we have great difficulties to surmount.

Having selected proper organizing committees and given them necessary funds to carry on the work, empower them to act I would say almost absolute power. When your committee runs against unforeseen stumps they can not wait for another annual meeting to get instructions how to pull up or get around that stump. They must act, so give them full power. Here is the weak place—the people can not or will not see the great difficulties in the way, get discouraged, or jealous, or fault-finding.

In organizing, remember that there are State and other laws to comply with, there are business customs that you can not ignore, that others have rights as well as you, and that your purpose is not to set arbitrary prices and make extravagant demands. You want to get in touch with the whole world so far as possible, for in these days even oceans do not separate neighbors and co-operators. Strive to understand each other. Help others and thereby help self. Two, three, or more, producers should sell together. Do not think for one minute that there is or can be over-production—no, never, while our neighbors just across the waters are starving by the millions.

When the bee-keepers are fully organized in a co-operative way, the head national office will know what you and I are doing, north, east, south, and west. The sub-State offices will know what is known at the general head, and in turn transmit to the various local branches or to the individual members. Tho there is never over-production, there is lack of distribution. Let us then co-operate that we may every one of us know what the crop is in every part of our land. Let the distribution be equal, and the prices proportionate according to supply and demand.

Is it a mighty undertaking? Yes, but results would be mighty. Will it harm anybody? Yes, just about as you are harmed by the complete postal system that takes in almost the world and carries your mail almost for nothing.

Do you catch the spirit? Then proceed to co-operate. Some are now at it, but hampered by the utter indifference, jealousies, or greed, of the many. To help a brother helps you; to tear him down destroys both. R. C. AIKIN.

Pres. Root—The matter is now open for discussion. Mr. Aikin comes from a State where they have an organization that carried out some of the ideas he has advanced here. They are not merely theoretical, but they are put in practice and do produce results. Many of you probably have not had any experience in this line and possibly do not care to discuss it.

Pres. Root—Dr. Mason has a matter that he wishes to bring up before the Convention before we close. Are you ready to present it at this time?

(Continued next week.)

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

The Premiums offered this week are well worth working for. Look at them.

Contributed Articles.

Pure Italian Bees—Old or Young Bees in the Super—Swarming.

BY G. M. DODDLETT.

A CORRESPONDENT sends in some questions and wishes me to answer them thru the columns of the American Bee Journal. His first question is, "Can a five-banded queen be bred—or a queen whose bees are five-banded from pure Italian queens?"

I unhesitatingly answer no, for the simple reason that there is no such thing as a *pure* Italian bee or queen, when viewed in the sense of a pure race or variety, as the German or black bee is pure. At best, the Italian bee is only a thorobred; and that these five-banded bees have been produced from what was originally only three-banded or leather-colored bees, is a good proof that the above assertion is correct.

Perhaps it may be well for me to give right here a bit of history relative to these so-called five-banded bees—the "golden Italian" more nearly expresses what they are, for there are many queens in this country to-day which give bees whose abdomens are a solid golden or orange yellow the whole length, except the tip; no bands whatever to be seen as on three and four-banded stock. The history is this:

In the early seventies, H. A. King, then of Ohio, and Jas. M. Brooks, of Indiana, were breeding for yellower bees than the average importations of Italians showed. In 1872 I procured some of Mr. King's stock, and continued to improve them till near the eighties, the apicultural world having lost sight of Mr. King, meanwhile. At that time, by exchange, I procured queens of Mr. Brooks, and afterward, by purchase, got the last of his very best stock, he going out of the business. In the early eighties I sold one of the best queens I could rear, along the yellow line, to L. L. Hearn, then of West Virginia, he and myself exchanging more or less for the next ten years. And, if I am correct, all of the so-called five-banded bees, of *Italian origin*, that are in the world to-day, spring from the King-Brooks stock. Others produced the so-called five-banded bees by a promiscuous crossing of Cyprian, Syrian and Italian stock, but such have shown their origin by their bad qualities, to a greater degree than either parentage.

OLD OR YOUNG BEES WORKING IN THE SUPER.

The second question is, "Is it the old or young bees that work in the surplus arrangement? I had supposed it was the younger bees, but a neighbor contends that it is the old bees."

Tell that neighbor of yours, if he will try the experiment of changing a black queen for an Italian about June 20th, some year, noting the time the first Italian bee hatches, and on the forenoon of the 14th day from that time look at the entrance of the hive, he will find none but black bees issuing therefrom; while if he removes the cover from the surplus arrangement he will find nearly all of the bees there to be Italian. If he does not so find, his experiment will prove different from any I have ever tried, and I have tried such experiments several times.

When a colony is in a normal condition, I have found what Elisha Gallup gave in the American Bee Journal during the early seventies, to be quite correct, namely this:

Three days in the egg form, six days in the larval form, and 12 days in the pupa form, making a period of 21 days from the egg to the perfect bee. Very warm weather will hasten the matter, while very cool will retard. The bee when it first emerges from the cell does nothing but feed itself for the first day or two, when it commences to become a nurse-bee, preparing chyme for the larva; evaporating nectar, secreting wax, building comb, etc., till it is 14 to 16 days old. The young bee takes its first flight or playspell, marking its location, voiding its excrement, etc., when six days old, if the weather is favorable, doing this from 12 to 3 p. m., and it continues these playspells occasionally till it is from 14 to 16 days old, when it goes out into the fields as a field-worker, doing no more of the inside work of the hive after becoming a field-worker, unless forced to by a lack of nurse-bees, from some reason, and dies of old age

at from six to eight weeks from time of emerging from its cell, very few bees ever seeing seven weeks of age during the working season.

In the above I have not given the exact wording of Mr. Gallup, but the substance, as I quote from memory, not having the volume in which it appeared. No beginner, or older apiarist, should be without the knowledge contained in the above, for upon it hangs much that goes toward making the management of an apiary successful.

OLD OR YOUNG BEES IN A NEW SWARM.

Thirdly, the correspondent wants to know if the "bees composing a new swarm are all old bees," his neighbor claiming they are.

The truth is, that bees of all ages go out to make up the swarm, as is very easily ascertained by any one who will use his eyes with the view of finding out about this matter. I have seen the ground in front of a hive from which a prime swarm was issuing, covered with hundreds of bees under 12 hours old, which tried to accompany the swarm, but were not able to fly, so they went out on foot; and on hiving the swarm, a little inspection showed that it was composed of bees of all ages, from those 20 hours old, or bees just barely able to fly, to those with ragged wings, just ready to die of old age. In this, as in all nature, God made no mistake, when he showed bees how those of all ages should accompany the swarm, when they heeded the mandate, "Go forth, multiply, and replenish the earth."

By a careful observation of the bees and the inside workings of the hive, we can solve many of what seem difficult problems to us at first. And in the solving of these problems, we are growing up into our apicultural work in a manner that will make us finally efficient in every particular. Onondaga Co., N. Y.

Shipping Queens by Mail—Unusual Experience.

BY O. O. POPPLETON.

ONE is very apt to give a wrong impression whenever he allows himself to make a simple statement without giving an explanation or reasons for that statement. This was especially true of the statement I made during the late Chicago convention, while the question of shipping queens by mail was being discussed—that I had "abandoned the ordering of queens by mail." Of course, the inference was that the mails were responsible for the poor quality of the most of my queens obtained that way, which was only true to a limited extent.

For some reason which I can not explain, I have failed in getting even a fair proportion of queens that would do well. This applies only to the queens I have received since I came South—not to those received when I lived in Iowa. The fact that 15 or 20 years ago I could get queens that proved first-class ones, and can not do it since coming south, looks as tho there were some other reason than injury by mailing. I have had queens from breeders in the North, in the central Southern States, and in the extreme Southern, and the results seem to be the same. I wish some one could tell me the reason why queens do not do as well here as they used to do in the North. I don't mean that the queens seemingly reach me in poorer condition, but that they prove much poorer for real business.

Another, and probably my strongest reason for not ordering queens from a distance, is the fact that fully one-half of the colonies which have been given these queens have developed bee-paralysis. These queens all have been from the ablest and most experienced queen-breeders in the United States, and men against whom there can not be the least suspicion of having knowingly sent out diseased stock. This is another one of the unexplainable things, especially so, as I do not know of any one else having the same experience. I have had practically to rid my apiary of all stock obtained from a distance, and their descendants.

The last few years I kept bees in Iowa, there were few things I did in the apiary that gave me better satisfaction than did the use of early queens from the South. I used to use from 25 to 50 every season. I could not only get them cheaper during the first half of June, than I could possibly rear them, but the getting them earlier than I could well rear them enabled me to use them at a decided profit. My general method of management was to prevent swarming as much as possible (usually keeping it down to 5 percent or less), thus keeping most of my colonies large and strong during the entire honey season. Increase was secured by taking nuclei from the strongest colonies early in June—

usually before the white clover honey-flow commenced—giving them these queens from the South. These nuclei thus given laying queens so much earlier than I could rear queens myself, would do enough better more than to pay first cost of the queens, be in better condition for the coming winter, and save me all the labor and expense of rearing extra early queens. No practical honey-producer in the North needs to be told what this means.

I observed closely for years, and could detect little or no difference between the quality of these queens and those of my own rearing, some of them proving among the best queens I ever owned. Were I now keeping bees any where in the North, I should make a very large use of early queens from the South. I should, of course, get them from as able and careful breeders as I could, and I don't think I should have any special fears of injury to queens in the mail.

Why queens would reach me all right when I was in Iowa, and don't do so in Florida, is one of the unexplained mysteries of bee-keeping. I only know the facts, not the reasons therefor. Perhaps some of the readers of the American Bee Journal can give us more light.

No. 13.—Interesting Notes on European Travel.

BY C. P. DADANT.

I HAVE well-nigh exhausted my subject, unless I take you on the ocean with me, or unless I take you to the place of my birth and make you acquainted with the companions of my young days, and show you in detail the narrow, winding streets of the old city, or the lonely rampart walls. You would wonder at the lack of life in their business streets, but would admire the whiteness of the houses, where coal smoke is unknown. You would wonder at the numbers of roaming dogs, at the habit the people have of walking in the middle of the street, owing to lack of room on the sidewalk where two people can not pass each other without one of them having to step off into the gutter.

In bee-culture you would see but little of interest, and yet we could not very well do without Europe and European bee-keepers. Did they not originally invent the movable frames, which Langstroth only made more practical by hanging them free from the inner walls all around? Did they not invent the first rudiments of comb foundation? Did they not give us the honey-extractor? the perforated zinc? Do they not, from time to time, give us the most interesting scientific experiments? The microscopic studies of Count Barbo, of Milan, made into 32 lithographs some 25 years ago, are yet at the head in the way of plain descriptions of the anatomical structure of the bee. But for practice, for production on a large scale, with the most economical results, give us America.

No. 2.—Bee-Shed of Mr. F. M. Wagner, of Adams Co., Ill.
See page 137.

But it is strange to see the very deep ignorance of the masses concerning America, on the Old Continent. Somehow they have a very clear idea that we are all millionaires, all Vanderbilts, Goulds, or Rockefellers, but they can hardly separate our millionaires from the Indians and the buffaloes. To them the United States is a country full of machinery and wealth, and yet half savage. The geography of the new continent is one of the things to come. They have a faint idea of the location of Chicago—somewhere near New York, or on the big Salt Lake. After two months of travel I had to give up the idea of enlightening any one as to where I lived by saying "in Illinois." So I had become accustomed to using the term, "On the Mississippi." Once while traveling thru England I met a gentleman, who, after I had given him that answer, said, "Oh, very well. Do you live above Niagara Falls or below?" That is about the extent of the knowledge that most of my French acquaintances could show of the geography of the United States. Yet they are all very well acquainted with countries that seem to us rather remote. Africa, Madagascar, Siam, and China, seem to be very familiar. But those places have not built up as America did, and what answered in their geography 50 years ago is still about right at this day, while the growth of America makes a new map necessary every 10 years.

A reader of the American Bee Journal puts this question to me: "How would you like to go back to Europe to live?" Not at all. America is the country for me. I should like to re-visit the places I saw—I admire the beauties of the European cities, of their buildings, which are certainly more artistic and in better taste than our plain, square brick boxes, which we call business houses or factories. They do not have a 20-story skyscraper by the side of an ugly 3-story square brick house as we do here; and around their monuments it seems as if a part of the ornaments had been lavished on all the surrounding buildings. This is true of either London or Paris. But give me America for pluck and enterprise. Give me America for a neat farmhouse, with a good barn far enough from it to keep the pigs and the manure smell out of the front yard. Here we have no peasants and there is an opportunity for every one.

America, in my mind, has been made what she is by her cosmopolitan condition. She draws from everywhere. All languages are hers. All nations join here, and each brings the knowledge and the views from his own. The Dane and the Spanish, the Italian and the English, the French and the German, all bring their customs, their habits, and from the friction of all these elements light is evolved. America is especially prone to adapt herself to all sorts of things. Nothing is good enough for her if something better is to be had, and altho we must acknowledge that the first results of

No. 1.—Bee-Shed of Mr. F. M. Wagner, of Adams Co., Ill.
See page 137.

this mixture of so many things, are many incongruities, yet the general good is sure to come from the apparent chaos. It matters not whether a thing is English or German, or French, if it is good it is accepted here; while a good thing, over there, will not be acceptable if it comes from antipathetic sources. "We have always done this way" is a very usual reply.

And not France alone is slow to take a proposed progress. The Anglo Saxons, who would have us think that they lead in every sort of progress, have strenuously opposed the introduction of the metric system, or of the decimal system in their money, because it was not decidedly English, no doubt, and they stick to their shillings and pennies and yards and pennyweights, while America bravely accepted the metric system, just because she saw that it was good. Visit an American farmer, then stay away 10 years and when you come back none of his implements of cultivation will be the same as 10 years before. He has outprogressed them all.

Even our new spelling reform shows that we are not content to remain stationary. I lately bought a new book, "Newest England," which treats of New Zealand and the wonderful reforms they are making there, faithfully trying co-operation, government ownership, and enough different forms of socialism to scare any conservative. Well, the writer of this book, who seems to love progress, still uses the English spelling—"valour, labour, neighbour, fervour, favourable, plough." If we have dropped the useless letters in so many words, why fall back—why not keep on improving? Or had we best go backwards and write "myrrour" for "mirror"?

But if the Europeans are slow to take hold, there is room for improvement here, too. The country is new and we try to go fast—too fast in some things. Our structures are often flimsy, our bridges insecure. Our roads are horrible, our architecture a salmagundi of all ages and styles. With our excellent railroad coaches, we have the most inefficient and expensive transportation. Our express companies "skin" us to the quick. We need parcel posts such as in Europe. While passing thru Paris, when first arriving in Europe, we had to give out some linen to wash, but could not get it back in time for our departure for the country. "I will send it to you by parcel-post," said the laundry-woman. "What, twenty pounds of linen?" "Why, yes, it will cost you 10 cents." And, sure enough, we received our linen, by mail, 20 miles away, for something less than a cent a pound.

While in Switzerland, a friend loaned me an umbrella, to go some miles in the rain. I askt how I could return it to him. "Oh, by mail." "By mail?" "Yes, it will cost you four cents."

How many of my readers know that we can send a half pound of samples of merchandise to any point in the Postal Union for half as much as it will cost to send the same package to our nearest post-office? Half a pound can be sent to the other side of the earth, or to the Fiji Islands, for four cents, while it will cost eight cents to send it to the post-office next to your own, in your own county. Yes, yes, America can learn something yet.

The Long-Tongued Fallacy as Applied to Bees.

BY R. C. HUGENTOBLE.

ADMITTING that long tongues in one species of animal life can do wonders in extracting sweetness, and carrying it to their homes to be evaporated, so as to make it more palatable to those who are fond of this sort of luxury, I am still extremely slow in applying this principle to *Apis mellifica*. It has been argued with much show of reason that the enormous yields of certain colonies of bees over all others, is attributable to their longer reach of tongue. The micrometer has argued long and eloquently in support of this theory, and the honeyed jury (I dare not say jurymen) have been deeply moved by the long tongue of counsel, and are actually measuring tongues with one another! It is not yet decided which has the longest tongue.

In order to defend the above theory successfully, it will be necessary, in comparing the results of labor, to have the short and the long tongues engaged on a flower whose chalice refuse to yield up any or all of the coveted treasure to the short tongues, and willingly bestow it upon the long ones.

In the summer of 1897, when the hills overlooking our town were robed in white, and guests by thousands sat down to the banquet of the flowers amid a glorious burst of

harmony, and drank the health of the same, I had one colony that gathered 140 pounds of nectar, choice enough for the gods. The average per colony of my entire apiary was 50 pounds. Was the large amount gathered by one colony due to long tongues? I answer no. Can not all honey-bees drain the chalices of white and sweet clover? And even if they could not drain the sparkling cups emitting inviting odors, what time be lost in such a sea of flowers? What need of cistern-pole when full unto the neck?

Again, in 1899 I had two colonies which gathered 100 pounds—double the amount stored by any of the balance of the apiary. That year,

Smiling May, she promised me that I might smack my lips;
But later on grew cold toward me, as love to hate oft skips;
And finally, with back to me, as she was going out,
"I'll back again next season when time signals thee to rout."
So, sore disheartened then was I,
But when May's sister came along,
She sang me her sweet-clover song
Which pleased my ear and filled mine eye
With jydrops for another year,
Until sweet June should reappear.

So melting poetry to prose, we had a fine flow of nectar from a 20-acre field, 1½ miles to the north, which had been furrowed by a flood and planted by that ready occupant—sweet clover. Learn of him thy opportunity to watch, and hold on with his might. He, an ardent lover of thin soil, sent his servants on weighty errands after treasure deeply hidden; which, when found and carried up, did intoxicate with delight my teeming kingdoms which, when frowning cloud and wind bore down on them, *en masse* came sailing on low down, till at flood-tide, they filled the main street of our town, scarce over my low head! Fair sight! Well worth a poet's eye!

We conclude then, that the superiority of one colony over many others in amount of nectar gathered, is due, not to the superiority of organs employed, but to superior industry which characterizes not only families and individuals in the lower kingdom of animal life, but families and individuals in the higher as well; and to argue that, in white clover and sweet-clover flows extending over periods of five weeks and three weeks, respectively, a particular colony manifested superior results in amount of labor performed because of a superior organ in its individuals, would be manifestly an error. Let us remember in breeding for long tongues to gather a doubtful amount of red-clover nectar (for the meager results from the bumble-bee indicate no purple goblets filled), that the characteristic energy of colonies is not dependent upon long tongues, tho they may accompany them. Nature, it seems, in the providence of God, has placed an apparently insurmountable barrier between *Apis mellifica* and the sparkling nectar in the rosy chalice, which, if overcome by the ingenuity of man, would doubtless yield some nectar, but, taking all things into consideration, be undesirable to all.

Hamilton Co., Ohio.

Cuban Bee-Experiences—Honey and Wax.

BY GEO. ROCKENBAUGH.

THE rain has been coming down in torrents all day, making one feel like doing something desperate, but instead I came up here on the peaceful mission of writing to the "Old Reliable."

April 10, 1900, I thought I was going to leave Cuba for good, never to see my bees again. I was the most disappointed bee-keeper that ever struck this island, as it was no trifle to lose 475 colonies all in 10-frame hives with two supers on each, and each colony containing a young queen. When I first began to work this apiary some of the hives were rotten with what I pronounced foul brood, as some of the bees were shipped here from Havana city. But I do not now think that it is foul brood, as I tried the McEvoy plan but made a failure of it. Some of the native bee-keepers pronounce it chilled brood, pickled brood and bald-headed brood, caused by pollen that is poisonous to the brood.

Every colony that I have is very badly affected with paralysis, which is probably also caused by that same poisonous pollen, as their abdomens are swelled, and they act as they would in a bad case of constipation. I have tried many remedies, but none proved of any avail.

When I arrived here the second time—Oct. 15th—there were only 170 colonies left, the others having swarmed out, and the hives were badly cut inside with moths. I have extracted about 10,000 pounds of honey up to this time.

I have not been at all successful here in rearing queens on the Doolittle plan.

In Gleanings in Bee-Culture, T. Smith says that Editor Pender, of Australia, gives his experiments, and claims that 4 pounds of honey will produce one pound of wax. What a foolish thing to put into type, and how unreliable the statements are. I claim to be one of the sugar-honey experts of the United States, and I will give a more reliable statement as to how many pounds of sugar is required to secrete one pound of wax. I have written the following rule which can be relied upon as very nearly correct, according to my knowledge and judgment.

Twenty-four cubic inches of comb will hold one pound of honey, and one pound of comb honey contains one ounce of wax; therefore one pound of secreted scales turned into comb will hold 16 pounds of honey.

Now I am going to contradict myself right here, but let me digress a little. I don't know how it is, but it is a fact that it requires 3 pounds of sugar to produce one pound of comb honey. I have had good, strong colonies that have been fed with sugar syrup from June 10th to Sept. 10th—a Heddon feeder kept full at all times—yet I could never make the best colonies store much over 200 pounds of comb honey each.

Bees that are good comb-builders require about 12 pounds of honey to make 1 pound of wax, and I have had bees that were supposed to be poor comb-builders that required 16 pounds of honey to make 1 pound of wax.

From the foregoing one can readily see that producing sugar-honey, or feeding "any old thing" to produce wax, does not pay. Cuba, Jan. 15.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Saccharin as Bee-Food.

Some time ago I saw some remarks about saccharin as a bee-feed. Is it any cheaper than sugar for bee-feed? or is it injurious to bees? Where can it be obtained?

INDIANA.

ANSWER.—Saccharin is said to be 300 times sweeter than cane-sugar, but I think you will find a dollar's worth of granulated sugar better than a dollar's worth of saccharin for the bees. You can probably get it of your druggist. It will cost you something like 300 times as much as sugar, and while you may have as much sweetness in a pound of it as in 300 pounds of sugar, you would by no means have the same amount of nourishment. The amount of carbon would not be present.

A Colony Taken From a Bee-Tree.

I found a bee-tree last fall rather late in the season, and I didn't like to cut it, but I was afraid some one else might come along and not think the same as I did. So the next day I went to work at it. I didn't think it would amount to very much, but I was after the bees, so after I cut the tree I got the hive ready to put in the bees. I was very careful about the work. The colony didn't seem to be very large, but after I had an opening big enough to look in, I was very much surprised. In place of the hive, I had to get two wash-tubs and a pail. Such a sight—nothing but honey, and yet plenty of bees also.

After I had all the honey out, I started to coax in the bees, but they wouldn't come. I had an 8-frame hive full of honey. I got them in once, all but a handful. I thought perhaps the queen was among them, but I could not find her there, and they all came out again. By evening, when it got a little cool, they took up a march to the hive once more, and very nearly all went in. Some got under the log.

I left the hive until the next morning, when I went back to look after the bees. When I got there they just started to come out, but I closed up the entrance and took them home, and placed them along side of my other bees,

and opened the entrance again. They started to fly just as fast as they could get out, for about two minutes, then they stopt. There were plenty of bees there yet, so I sat down and watched them. Pretty soon, to my great surprise, I saw some of the bees coming back with pollen on their legs.

Now, what I want to get at is this: Do you think the queen is there? Why should they carry pollen, and not my other bees? If they have no queen, will it do to let them out all winter? They seem more noisy than my other bees. ILLINOIS.

ANSWER.—Very likely the queen is all right. In any case it is best not to disturb them till spring. Then when bees fly freely, and you find brood in other hives, you can decide whether the queen is present by looking whether there is any brood. If no brood is present it may be your best plan to unite it with one of your weakest colonies that has a queen.

Spacing Hives Spring Feeding.

1. Is four feet from center to center too close for the hives in the row?

2. Will feeding bees when they are flying early in the spring give satisfaction? If not, why? ONTARIO.

ANSWER.—1. No; but here is something a little better that will allow more hives on the same ground. Set two hives side by side, with only two or three inches between them. Then leave a space of three or four feet and put another pair of hives close together, and so on. If you place a number of hives with only a few inches between them, there will be trouble about entering the wrong hives, but there will be no trouble when only two hives are placed close together.

2. Properly managed and under proper conditions it may give satisfaction. If weather is warm enough for bees to fly daily, and there is nothing they can get in the fields, the feeding may be a decided benefit. If the weather is somewhat chilly, so the bees do not fly freely, altho flying to some extent, feeding may induce the bees to fly out and become chilled.

Ventilating the Supers.

I have been keeping bees for six years just playing at it while in the ministry, and so keep only a few colonies. I am wintering 8 colonies, using dovetailed Langstroth 10-frame hives with Hoffman frames. I appreciate your answers to others very much, and so will ask one or two myself.

If a hole were bored in the end of a super with wire-cloth tacked over it—

1. Would the ventilation be helpful or harmful?
2. Would light entering in be helpful or harmful?
3. Would you advise boring a hole there?
4. If advisable to have a hole there, how large should it be?

ILLINOIS.

ANSWERS.—1. I don't know.

2. I don't know.

3 and 4.—I would not advise it.

Now that I've answered all your questions, suppose we sit down and talk over the matter a little. Allow me first, by way of parenthesis, to congratulate you on your good judgment in choosing something so interesting to "play at" while working in the ministry. It seems just a little strange that there is so much difference between this country and Europe as to the proportion of the clergy engaged in bee-keeping. In Germany, especially, a very large number of leading bee-keepers are clergymen or professors and teachers in schools and colleges. When I say "leading bee-keepers" it does not necessarily follow that they devote their time mainly to bee-keeping, nor that they keep a large number of bees. But in their moments of leisure they give earnest attention to the subject, and are among those who have added most to our stock of knowledge on this most interesting subject. Father Langstroth, who brought about an entire revolution in bee-keeping, belonged to the clergy. So does Dr. Dzierzon, who has done more than any man living to advance bee-keeping.

But now to our subject. At one time I was on a visit to Adam Grimm, who was one of the leading apiculturists up to the time of his death. He was putting on his plus boxes it was before the day of sectionists, and when he put the hive-cover over the boxes he propped up the back end of the cover something like an inch. As he was propping up one of the covers, he looked up and said in his earnest

way, "I consider that very important." Mr. Grimm did not tell why he thought it important, and I think I didn't know enough to ask him. But I thought he was a safe man to follow, and as I adopted sections very shortly after that time, using double-tier wide frames with 56 sections in a super, I provided an opening as nearly like Mr. Grimm's as I could by shoving the super forward so as to make a space of one-fourth to one-half an inch at the back.

This worked quite satisfactorily, but a super with 56 sections was very heavy, and on some other accounts I was led to change to the T super, which I now use. With this I still kept the opening at the back by shoving the super forward. A difficulty that I had before noticed to some extent seemed now to be aggravated. The sections next the opening proceeded very slowly compared with the others. The opening to the outer air at this point prevented the bees from building comb to a considerable extent. So I gave up this opening, closing the hive entirely above, relying only on the ventilation from below.

After this change, however, the amount of swarming increased a great deal, making it look as if the ventilation right thru the hive had a good deal to do with keeping down swarming. Another thing helps greatly to strengthen that belief. For years I have generally had a few colonies that were allowed to have three or more stories, with a large opening to each story, the combs being used for extracting, or kept as store-combs. I do not remember that one of these colonies ever swarmed, and I attribute this immunity from swarming in a great measure to the large amount of ventilation.

In the light of all this, it would look as if it would be a good thing to have the ventilation you propose, providing you are working for extracted honey, the air and the light not being objectionable. With comb honey the hindrance to comb-building stands in the way. Wire-cloth over a ventilating hole is not needed, and the bees will be pretty sure to fill it up with bee-glue. It is hardly advisable to bore a hole in any case, for you can get better effects by shoving the super front or back. That distributes the ventilation, instead of having it all at one spot with the hole.

Questions on Swarming.

In your book, "A Year Among the Bees," which I bought of you in the spring of 1887, you say on page 49, "When it comes time to put on supers, they (brood-frames) are reduced to 4 or 5 frames."

1. Do you still practice this contraction of the brood-chamber before swarming?
2. When a colony swarms do you have the swarm in a contracted brood-chamber?
3. And if contracted or not, do you use starters or full sheets of foundation in brood-chamber?

NEW YORK.

ANSWERS.—1. Alas for the changeableness of bee-keeping—it is not safe to count on doing anything to-day the same as 15 years ago. Strictly speaking, I do not practice contraction now. Up to the time of putting on supers I give all the room needed for brood-rearing, even to two stories of 8 frames each, if the bees will use it. At the time of putting on supers I take away all but 8 of the best frames of brood, if the colony has more, and give it enough to make 8 if it has less. Some would say that is contracting, and some would say it is exchanging room in the super for room below. At any rate, my practice is to have each colony have 8 frames of brood at the time of putting on supers.

2. If I were having a swarm, I would give it four or five frames, and fill up about 10 days later.

3. I always use full sheets of foundation. I might do otherwise were it not for just one thing, and that is that I want to be sure of all worker-comb. One of the ablest of German bee-keepers, the late C. J. H. Graefenhorst, practiced giving a swarm four or five frames with narrow starters, counting that very little drone-comb would be built in them, and when they were filled giving enough combs or full sheets of foundation to fill out the hive.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journal can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

THE BEE KEEPER AND THE BEE-SUPPLY DEALER.

In "Colorado's" letter and its replies, on pages 69 and 70, we have a first-class rumpus, albeit by no means a new one, and not likely to become a closed incident very soon. How much human nature we can see in man when we get him in print once! Man who doesn't like a situation seldom fully appreciated by the man who does like it. Just hear the latter fellow's replies pop off—as he talks of buying a car-load of supplies "sight unseen," and a thousand miles off. "Not so bad off as he imagines." "Do not consider the dilemma of our Colorado friend a serious one." "Very little trouble in getting or giving satisfaction." Ahem! And, in good sooth, if the fellow is plump and candid enough, we rather like him, at least to the extent of a good laugh. "Why should I contribute to make it perfectly safe for my customers to order of my competitor? If I have given them satisfaction, and no cause to complain, let them keep on buying of me." And when we get reminded that much of the trouble arises from our own too fierce cheapening of everything we would do well to stop and consider—yes, a large amount of considering. First a pinch of "live," and then a pinch of "let live" should go in the peace-pipe which we are to smoke. The two little girls who never quarreled reported their secret to be, "Addie lets me and I let Addie." But, as to the manufacturing Addie, we don't quite see our way clear to "let Addie" while she is in her present frame of mind. For one thing she doesn't realize what a prodigious lot of mistakes—some annoying, some expensive, some both, but not entirely spoiling the goods—go out to her absent customers. I take it that part of these are scolded about a little, and salvaged over by a little apology, and the larger part never mentioned at all. Never mentioned because few of us enjoy making complaints, when we know in advance that they will never eventuate in anything except talk. A present-at-the-factory customer would say: "Fix this and this, and I'll take a thousand; otherwise I'll not touch 'em with a pole."

Remedy? Not sure there is any. The Falconer proposition seems the best mentioned. Pay half, and deposit the other half to be paid on satisfaction being reached. How would it do to employ some bee-man who lives within 25 miles of the factory to go and see your car-load of supplies on board? He couldn't see with your eyes nor feel with your feelings, as to faults mainly annoying or ill looking, but not seriously affecting the utility of the goods.

A THICK THE BEES PLAYED.

That trick which Mr. Bauckman's bees played, page 60, was a very unusual one. It is unusual for a swarm to plunder the home hive, and again unusual for a plundered hive to survive and amount to something later on.

KEEPING BEES ON SHARES.

Yes, that's so; the man who is keeping your bees on shares can not be dissatisfied very well if unsatisfactory. Also, if the season proves so bad as to afford no hope of anything to divide, he might take himself off without saying a word. You think your bees have a keeper when they are totally neglected. Page 66.

SO UNFUTTERABLY UTTERED, YOU KNOW.

The latter case being so "utterly utter," and all that's fairly utterable being already uttered, I think I'll skip it, and forbear to utter. (Of (tho' our bread findeth butter).

THAT GERMAN UNCAPTING FORK.

So Mr. Krentzinger has an uncapping fork—but does not tell his editorial visitor whether he has ever "made it go," or no. Suspicious circumstance. Forks that never "more" are not as a class a very hopeful class. Perchance the uncapping fork may be the idea of that kind of amateur who wants to lift off the cappings without taking any of the honey—and the amount of time it takes to do it may not appeal to his mind very strongly. Page 68.

Good Prospects for a Crop.

My bees are wintering very nicely. They had a good flight Jan. 30th, and prospects are good for a crop of honey this year. I do not think white clover has been damaged any this year. G. GREENE.

Sioux Co., Iowa, Feb. 14.

Worms Destroying Alfalfa.

Bees are in fine condition. They bred up strong in October, so with plenty of first-class stores I expect them to come out all right in the spring. They did remarkably well last season after July, but almost nothing earlier. Worms took most of the first crop of alfalfa; I am told that these worms drove at least one family away from their dwelling, crawling up the north side of their dwelling until they were two inches thick on the roof.

Our Colorado people are as much down on sweet clover as I was some years ago when I wrote it down in the American Bee Journal, and got a good drubbing for so doing. I am going to plant two pounds of it on my own land, "just for greens," and chance it. Some of our cattle men say if I do I will die.

The bee-industry in this country is in its infancy, tho' I understand there are about 4,000 colonies of bees in the country. About a half dozen people own from 50 to 350 colonies each, and the balance are scattered mostly among people who are "just experimenting."

The prospects for the future are very bright indeed.

We have lately organized as the "Lamar, Colo., Bee-Keepers' Association," of which your humble servant has the honor to be corresponding secretary. JAMES H. WING.

Powers Co., Colo., Jan. 18.

P. S. Poggane (Tarlow) got back from Alaska in September, and says he found bumble-bees, also mason, carpenter, and faller bees, 40 miles above the Arctic Circle.

J. H. W.

Bee Keeping in Clarke Co., Wash.

Mr. G. W. Durkee, of Wisconsin, a reader of the American Bee Journal, has sent me a letter with inquiries regarding bee-keeping in this part of the State of Washington, and thinking that there may be other readers likewise interested, I beg to answer Mr. Durkee thru this medium. The questions are as follows:

1. Are you located near the Columbia River?
2. From what does your main honey-supply come?
3. Do you have basswood, white clover, sweet clover, and honey-dew?
4. What is your average surplus per colony in a fair season?
5. What does honey sell for?
6. How do you winter your bees?
7. What do sections and foundation cost out there?
8. What are bees worth per colony?
9. Is there any demand for a bee-keeper in Clarke County?

G. W. DURKEE.

ANSWERS. 1. Yes, on the edge of the highland joining the lowlands along the river. White clover, fire-weed, and Spanish-heath furnish the main part of the surplus honey, in the order named.

2. We have no basswood and sweet clover, but only in a great while we get some honey-dew, very rank in flavor. But in average winters this stuff is all right for stores, as bees here are seldom prevented from having a good flight for more than a couple of weeks at a time.

3. This question I am unable to answer further than what I have stated in my reports in this paper.

4. Look up the market quotations in this paper for San Francisco, and add to those prices about one cent for comb and one-half cent for extracted honey, and you will come very near the prices that honey-sellers at wholesale in Portland, Oreg., or if you are not your own salesman you will have

They Never Fail

You cannot afford to risk good eggs in a poor incubator or poor brooder. There is no need of doing it. The

MARILLA

Incubators and Brooders

never disappoint. They are made of good material, in a solid, thorough manner, and have a perfect system of circulating heat and moisture that they are absolutely certain in results. They are sold on a positive guarantee. Your money back if you want it. Send two cents for catalogue and learn why they are the leaders. Twelve years' success behind them.

to deduct freight, commission, breakage, etc., to get the net prices realized by the producer.

5. I winter the bees in one-story single-walled hives. I put two sticks of 3x4x11 inches crosswise on the top of the frames, then a burlap floor cloth, and one-half dozen double sheets of new-paper and the flat dove-cover, and on top of this the shade-board to keep off the rain. In the coldest part of winter I leave the whole entrance 3x12 inches open, and when spring arrives, generally in February, I again contract the entrance to about 2x2 or 3x2 for an average colony, as by this time when the bees are flying more or less every day, they are better able to keep their combs and inside of the hives free from dampness and mold, and it also assists the bees in keeping up the temperature to rear their young. I have no doubt it would pay in this mild climate to use more packing on the top of the brood-frames than I do, for then so much ventilation would not need to be given thru the entrance in cold weather, and the consumption of winter stores would not be so great. However, my bees have come thru the winter in good condition, with a loss of a very few colonies, and I have never used more than mentioned above.

6. Sections are high in price. I have a 1901 catalogue issued by a firm in Portland, Oreg., in B. No. 1 sections are quoted \$4.75 per 1,000, and foundation from 30 cents per pound for heavy brood to 65 cents per pound for extra-thin, in 10 pound lots. If you come out here to start in bee-keeping, I would advise you to purchase a Barnes foot-power saw and make your own sections, frames, hives, etc. Lumber is cheap. While you are in the woods, spruce is plentiful, cheap, and good to make sections from. I have found Oregon and Washington cedar to be the best material I know of for hives and frames. Any man with average intelligence can make his own hives, frames, sections, etc., with the saw mentioned above, even after a poor season, when money is scarce with the bee-keeper. Of course, if you haven't it I would advise you to get the "ABC of Bee Culture," and read the directions there given for making hives, and the proper use of the Barnes saw. (As I have no ax to grind, I hope the editor will not object to the special recommendations given to the saw and the book, as I give it solely for the benefit of bee-keepers, and write from actual experience. I feel that I owe so much of my success in bee-keeping to the American Bee Journal, with all its beloved and able writers, that I want to do what I can towards paying a little of my debt.)

7. Bees can be bought in box-hives from farmers here at all prices, from \$1.00 to \$2.50, but of course it takes time to gather up enough bees in that way to make a reasonably good start, and you will perhaps also have to call on bee-keepers who ask from 55 to 88 per colony for bees in one-story dovetailed hives.

8. There is very little territory in Clarke County worth anything for a specialist bee-keeper that is not already occupied, but there are good locations farther down and along the Columbia River.

T. H. WAILE.

Clarke Co., Wash., Jan. 26.

Bees Cleaning Up Unfinished Sections

As autumn was closing I had 50 pounds of honey in unfinished sections. As I desired to use these for bees the coming season, I concluded to let the bees empty them by placing them in tiers and myself in the same position, and allowing but one bee to enter at a time; but having a rich neighbor owning bees on the square above me I own mine on the square also, the very much outnumbered, I concluded it would be unwise to allow him even a small sphere of influence; lest he overruin my kingdom with his own; so I began forthwith the tedious process of uncaping and extracting the entire lot of unfinished sections. After they were all uncapped and tiered about 50 feet to the westward of my western row of hives, and the bees had been working on them some time, I was attracted by the buzzing industry about that bee-space. Watching with high admiration the opposing columns, as first one, then the other, gained the ascendancy, now pouring

You Can't Afford to Guess

at results in the poultry business. If you fail to raise the chicks, you simply have no business. The way to be absolutely sure about getting the chicks is to employ a Cypheer Incubator in your hatching. We guarantee them to last 10 years and to outlast any incubator made. The best way to know about it is to read our 52 page "8811" book, "Profitable Poultry Keeping," has 20 illustrations and covers the entire subject. We send it for 10 cents in stamps or 14 for 25. Cypheer model free. Address: Mrs. C. J. CYPHER, INCUBATOR CO., Chicago - Ill., Watertown, N. Y., Boston, Mass. Please mention Bee Journal when writing.

Drugs and Chemicals by Mail. We produce herewith, very inadequately, but as best we can in black and white, the beautiful cover of the Heller Chemical Co.'s new catalog. It is one of the handsomest, and certainly the most complete of the kind we have ever seen. The cover is lithograph in many colors on heavy tint; the book contains 144 large pages, 1520 illustrations, and gives cut-rate prices on more than 15,000 articles—household and standard remedies, pills, tablets, livestock and poultry remedies, toilet preparations, rubber goods, oils, brushes, and in fact everything found in a

complete drug-store. The prices quoted will be a revelation to our readers, as they are from 15 to 75 per cent below those of retail dealers. The book should be in every house in the land, for it will save the purchaser many dollars in the course of the year. The Heller Chemical Co., the only mail-order drug-house in the world, is reliable, and our readers may depend upon fair treatment. Send to cents for this catalog, which will be refunded with your first order. See their advertisement in another column. Address: Heller Chemical Co., Chicago, Ill., and please mention this paper in writing.

The Emerson Binder.

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

into, now out of, now gorging the entrance. I discovered that the rich man was becoming richer, and the poor man poorer. As a neighbor sometimes keeps his own by knowing what a neighbor hath, so I have since done. Knowing that my neighbor's bees were all blacks, and a good share of mine Italians, curiosity was aroused until it stood on tiptoe. Peering from a window I beheld their black craft as they sped on their course toward their place of abode. Never was merchant-man so freighted, the loaded to the water's edge, and well-nigh undrinking. To and fro they plied twist rich and poor. Not a sail from Italy's sunny strand e'er hove in sight! My neighbor's blacks had found the treasure, staked their claim, and asserted "priority of occupation."

Again, last autumn's glow, I piled a score of hives up in three tiers. Italy's fair colors now flamed the breezes as they bore down upon the discovery, and sped to tell the news to ready listening ears that waited now to spread all sail. But three or four of my colonies were thus engaged, for the coming trader, while my neighbor's and 80 of my own were not playing an oar. Thus, it seems, that given but a bee-space the discoverers had planted their standard on the new-found shore, and taken possession in the name of their queen.

R. C. HENTZLEBER.
Hamilton Co., Ohio, Jan. 17.

Bees Did Fairly Well—12-Pound Cases.

I have 82 colonies of bees, 30 in 8-frame intended hives, and 52 in 10-frame hives. I intend transferring them all to standard hives. They are in fine condition, and have about 100 pounds each of honey to build up on this spring.

I have had some experience with bee-paralysis. I simply kill the old queen, and rear a new one from my bees. It takes within three years.

I sold honey in one-pound sections in 12-pound shipping-cases—the first ever sold here—and it went like hot-cakes; I could not supply the demand.

My bees have not done very well the past three years, tho I have secured from 1,000 to 1,500 pounds of honey each year, while my neighbors got none. Why? Because I take the American Bee Journal. When I first began taking it people laughed at me, but they have stopped it, as they see that I get the money, and I still take the Bee Journal. I can't get one of them to take it, tho. But let it still continue to come to help me out of my troubles, as it always has done.

A. R. YANDELL.
Scott Co., Ark., Jan. 30.

Requeening Red Clover Honey.

In requeening some of my colonies last season I took two frames with the queen from one of my strongest colonies, giving the remaining brood one of my imported queens from Italy. Thus I had good eggs and larvae from my first colony to rear queens from, and got a fine lot of queen-cells drawn out. On the eleventh day I took the queens from the colonies that I wanted to requeen, and by the next day the bees had learned that they had no queen. On the morning of the twelfth, after the brood had been exchanged, I cut out the queen-cells that suited me, putting one in each hive between two frames and at the top, taking care that the sides of the cells were protected, as I never knew the bees to eat a queen-cell at the end. Within three days the young queens had hatched, and the bees had received them, and in from five to eight days I had young laying queens. I purchased eight colonies by this method, and did not lose one. I tried a few on the nucleus plan after the queen had been laying, and lost two out of five, so I like the new way better if it continues to work as well as on the start. But if it should work as some of our experiments with the bees do, it may change my mind; for sometimes when we think we have attained perfection in some of our work with the bees, they let us know that we are not yet master of all their ways, and upset all of our plans. So I have learned that other creatures have some rights in the way of following the plans

in the blossoms. Can any one tell why there was not?

The absence of zero weather this winter (with the exception of one day—Dec. 31st), has been a very desirable feature in the wintering of bees in this locality. There were several days in November and December when the bees had a good, clean, slight flight, and many days when they couldn't fly they could move their positions inside of the hive, to reach their stores. This state of affairs almost insures safe wintering. Very little snow has fallen thus far (Jan. 31).

My losses in wintering during the winter of 1899 and 1900 nearly wiped my apiary from the face of the earth, hence my attention has been drawn to other means of making a living, yet the old love for the business still remains, and I am now giving up calling that I have followed for 20 years or more seems a hard thing to do. The pleasure one derives from a business he loves to follow is hard to estimate. Altho my losses have been very heavy during the past three years, I still take three of the best beekeepers, and have kept informed along the line of new improvements.

I am wintering my 22 colonies on the summer stands, in claff or double-walled hives, protected on the north and west sides by corn-fodder set up around them to break the north-west winds. If such protection had been given them two years ago, when my loss was so heavy, I think a large percent of them would have been saved. A high board fence, or some protection on the north and west, is very essential in wintering bees on the summer stands, and in the end saves many times the cost of such a construction.

Altho my bee-keeping experience extends back for more than 20 years, my knowledge is still quite thin. I learn something nearly every day, either from the bees or by the reading of the experiences of others in the bee-papers.

White clover abounds in this locality, and promises a fair crop next season. The yellow and white sweet clover varieties are also getting a start around here.

The "old Reliable" comes to my desk every week as regularly as the clock strikes the noon hour every day. I am glad to note that many improvements have been made in its make-up and in the valuable matter it contains from week to week. I wish all the readers of it, and the Bee Journal itself, a prosperous year and a beautiful harvest.

Cass Co., Neb., Jan. 3, 1914. J. M. Yost, Sr.

California Smiles.

I notice in a recent issue of the American Bee Journal that I am quoted as holding rather pessimistic views in respect to the rainfall and honey prospects in this State. Well, matters have changed since the publication of that, and now we are optimistic. Things are favorable and almost certain for a good honey yield.

We have had an abundance of rain during the past 10 days, and vegetation is coming forward with a rank growth. The sages, altho somewhat killed out during the past three years, are making a good growth, and a new growth is putting forth with vigor. Beekeepers are putting forth also, with the exception of a honey-crop. Bees are in demand, and I recently learned of the sale of 200 colonies for \$1,000 an extra-good price for this country. There has been over 12 inches of rain up to date, and more coming.

THE RAMBLER.

Ventura Co., Calif., Feb. 6.

1904 a Failure A Wheat Country.

The past season was a poor one for honey in this locality. I did not get any, and about the only man that did was an old gentleman that never takes a bee-keeper. He secured about 200 pounds of fine white honey; he has a near neighbor that raised alfalfa, and the bees got it from that source. I have tried to get him to take the Bee Journal, but he refuses, saying that if he did he would not change his way of keeping bees.

I have seen a good many beekeepers this winter, and all report 1900 a poor year, and most say it was a failure. Well, I had the fun if I didn't get a crop of honey. I will sell

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son. Each subject is clearly and thoroughly explained, so that by following the instructions of this book one cannot fail to be wonderfully helped on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us THREE NEW subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

a part of my bees in the spring, and run what I keep for comb honey.

This is a farming district, and the crop is mostly wheat. Last year it rained soon after the fields were cleared of crops, then the plowing began, and bee-feed was turned under before it had time to bloom. This county is the banner county of the State for wheat.

SAMUELSON STOTT.

Summer Co., Kans., Jan. 28.

Some Queen Experiences—Cooling Wax.

The question, Why should a colony refuse to kill the old queen when she has stopt laying, and a young queen has emerged, the colony finally swarming with the old queen that was clipt, there being no eggs or uncapt brood, and but little capt brood in the cells? was asked by me at the National convention, but as I was not in attendance when it was brought before the convention, I will relate the facts as they occurred:

It was the first week in August, and I was not expecting any swarms under the prevailing conditions, but while working in my store-house for bee-supplies, etc., I noticed a commotion among the bees, and upon investigation found a swarm in the air. I soon found whence they came, and as I wanted some increase I secured a new hive, which I placed on the old stand, putting the old colony on a new stand. The swarm soon returned, the old clipt queen being with them. After a little time I went to see how the swarm took to the new hive, and found nearly all of them clustered on the bottom of it, so I used the smoker to drive them back. I thought something must be wrong, so I opened the old hive and found a young queen, which I killed. Upon further examination I found that the frames did not contain a single egg or any uncapt brood, and but very little capt brood, and several queen-cells in which were queens about ready to emerge. I killed all the queens, including the clipt one with the swarm, and gave each colony young larvae from Italian queens from which to rear others. In about 8 or 10 days I became so dissatisfied with the Italian queen from which the larvae was taken that I went to one of the hives into which was put the frame of brood, larvae and eggs, and to my astonishment I found a line of queen-cells built around the lower part and on both sides of the frame. I counted them, and found that there were 60 capt queen-cells. I destroyed these and transferred the just-hatched larvae to the uncapt cells, and they were accepted and hatch into fine queens. I do not know if such things happen frequently, or whether they are freaks, but I know positively that the above occurred.

I bought and reared a number of queens during the past season, which were introduced without a single failure. I think there is no excuse for losing queens thru introducing, if the proper course is pursued, and precautions taken. Always be sure there are no queen-cells and no queen in the hive before releasing the new queen. Leave the caged queen in the hive two or three days, and let the releasing be done by the bees eating thru the candy. It is better to introduce queens during a honey-flow, as they are more readily accepted at that time.

In regard to the cooling of wax, I be-

lieve that the longer the wax is in cooling, and the longer it is in the liquid state, the clearer it is of dirt. Slow cooling might not make any difference in the quality of the wax after it had past a certain temperature, but fast cooling will almost always cause it to crack, and this I wish to avoid. As a rule, when I extract wax I have quite a lot of it which I pour into large pans placed upon the floor, and cover with sacks and such available material, and it is generally satisfactory.

The honey crop was short in this locality the past season, and white clover was a failure. I have made a practice of stimulative feeding for several years, and I think it pays when properly done. The early spring and until after fruit-bloom was exceptionally good. After fruit-bloom I began feeding, using the Boardman feeder early in the morning. I continued to feed until within a week of basswood bloom when I discontinued, thinking the bees were getting enough from the fields to keep them up until the basswood flow. But by that time nearly all were light in honey, tho very strong in bees, and it took the first three days to fill up below. Then the weather became so cold that it threatened frost, and for about four days they stored but little honey. The colony on the scales stored 8½ pounds. There being but little fall honey, and October being such a warm month, bees flew nearly every day, using up their stores, so quite a number of colonies were a little light when the time

came to put them into the cellar. But we hope for better years to come.

I enjoy reading the report of the National convention, and I think all bee-keepers should be subscribers to the American Bee Journal.

G. H. FREY.

Linn Co., Iowa, Jan. 10.

YELLOW OR WHITE

Sweet Clover Seed

Free as a Premium

For Sending us One New Subscriber for a Year.

There has been so much written about both the white and the yellow variety of sweet clover, that we will simply say here that if one of our present regular subscribers will send us \$1 with a new name for this year, we will mail, postpaid, to the one sending the new name and the dollar, either one pound of yellow sweet clover seed, or two pounds of the white sweet clover. This is a good chance to get a start of both kinds of these honey clovers. Better send two new subscribers (with \$2.00) and get the three pounds of seed. Address,

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Feb. 19.—Fancy white comb, 16c; No. 1 white comb, 14½c; fancy amber, 12½c; No. 1 amber, 10½c; fancy dark, 10c; No. 1 dark, 8½c. White extracted, 7½c; amber, 6½c; 7½c; dark, 6½c. Beeswax, 28c.

R. A. BURNETT & Co.

KANSAS CITY, Feb. 19.—Fancy white comb, 16c; No. 1 white, 12c; No. 1 dark, 10c. Extracted, 7½c; amber, 7½c; dark, 6½c. Demand fair; receipts light. Beeswax, 22½c.

W. R. CROMWELL PRODUCE CO.,
Successors to C. C. Clemons & Co.

CINCINNATI, Feb. 9.—The market for comb honey is becoming very bare, although the prices have not changed. Fancy white comb is still selling for 16c; no demand for darker grades. Extracted is in fair demand; dark sells for 5½c; better grades from 6½c to 8c; only white clover brings from 8½c to 9c. Beeswax, 28c.

C. H. W. WEBER.

ALBANY, N. Y., Feb. 11.—Honey market is dull and cash prices are better than expected. The cold weather is bad for it. Comb, in good order, not candied, white, 15c; light, 13½c; dark, 11c; and buckwheat, 11½c. Extracted, white, 7½c; mixt, 6½c; dark, 5½c.

H. R. WRIGHT.

BUFFALO, Feb. 8.—Some more active this week, and may clear up on our market. Demand awhile ago. Fancy 1-pound comb, 15c; No. 1, 14c; No. 2, 12c; No. 3, 10c. Dark, buckwheat, etc., 8c; No. 1c. Beeswax, 25c. BATTERSON & Co.

BOSTON, Feb. 8.—Fancy No. 1 white in cartons, 17c; No. 1, 16c; No. 1, 15c; No. 1, with fairly good demand. Absolutely no call for dark honey this year. Extracted, white, 8c; 8½c; light amber, 7½c; No. 1c. Beeswax, 27c.

BLAIR, SCOTT & LEE.

NEW YORK, Feb. 15.—Comb honey is being well cleared up on our market. The demand has lessened to quite an extent, on account of the pressure, of the high prices which have been ruling. Fancy white still brings 15c; No. 1, 14c; No. 2, 12c; No. 3, 10c. Dark, buckwheat, etc., 8c; No. 1c. Extracted, white, 7½c; mixt, 6½c; dark, 5½c. California white honey, 7½c; No. 1c; light amber, 7c; Southern, from 6c to 7c; per gallon; buckwheat, 5½c. Beeswax steady at 28c.

HILDEBRATH & SEIGLER.

DETROIT, Jan. 19.—Fancy white comb, 15c; No. 1, 13½c; dark and amber, 12c; No. 1c. Extracted, white, 7c; No. 1c; amber and dark, 6c; No. 1c. Beeswax, 26c.

M. H. HUNT & SON.

SAN FRANCISCO, Feb. 6.—White comb 13c; 14c; amber, 11c; No. 1c; dark, 8c; No. 1c. Extracted, white, 7½c; No. 1c; amber 6½c; No. 1c. Beeswax, 26c.

Considering the light output of honey last spring from California apiaries, present offerings are of tolerably liberal volume and are mostly of amber grades. The market is slow at the quotations. It is reported on good authority that adulterated and imitation honey is being dealt out in considerable quantity, which accounts in a great measure for the very limited business doing in the pure article.

HONEY MARKET.—We may have a customer within a short distance of you who wants your honey or beeswax. We are in close touch with all the markets, therefore write us regarding your crop, stating quantity, quality, and lowest cash price. References—Either Bank here for any business man in this city.

Liberal Discounts to the Trade.

Reversing the Current. Some years ago by artificial means the current of a western stream was reversed, and it was thought a most wonderful thing. But it seems less remarkable to us than turning the tides of trade flowing in the opposite direction, and this is what has been done by the Reliable Incubator and Brooder Co., of Quincy, Ill. Artificial incubation originated across the water, but it has been developed, perfected, and popularized on this side, so that now thousands of incubators are shipped every year to foreign markets. No machine is more widely or favorably known abroad than the Reliable. It is a pioneer in its line; and while it often happens that those early in the field are outstripped by younger rivals, this has not been the experience of the Reliable, and their interests abroad have received a fresh impulse thru their splendid exhibit at the Paris Exposition of 1900. Their honors—medals and highest award—are a flattering recognition of this representative American industry. Their catalogs from year to year keep pace with the improvements made in their machines. They are now mailing the second edition of their 24th century catalog. It is one of the most complete compendiums of poultry appliances we have ever seen. A copy will be gladly sent to any reader of this paper on receipt of 10 cents to pay postage. The information it contains would cost many dollars if secured in any other way. Address, Reliable Incubator and Brooder Co., Quincy, Ill.

Gleanings in Bee-Culture...

Is an illustrated semi-monthly, 32 pages and cover,
at \$1.00 a year.

If you keep only a few bees you can't afford to get along without GLEANINGS IN BEE-CULTURE, as it will save many times its cost the first season. Better get along without almost anything else than a good bee-paper. There is no use in our telling how good GLEANINGS is, as it will speak for itself if you will only let us send you a sample copy for your name and address on a postal. If you once see it we know you will want it.

Look at Our Offers:

Offer No. 21.

For 25 cents we will send GLEANINGS 6 months' trial subscription to new subscribers.

Offer No. 22.

For \$1.00 we will send GLEANINGS for one year, and an untested Italian queen valued at 75 cents; but at this low price we reserve the right to send queen some time in July when we have a choice supply.

Offer No. 23.

For 50 cents we will send GLEANINGS from the time your subscription is received till Jan. 1, 1902, so that the sooner you send in your order the more numbers you will get.

Offer No. 35.

Gleanings one year and one untested red clover queen, \$2.00. Gleanings one year and a tested red clover queen, \$4.00; a select tested red clover queen and Gleanings one year for \$6.00. We will begin mailing these queens in June. Orders are already being entered and will be filled in rotation. Do not neglect to improve this opportunity and get some choice stock. Send your order early so you may get the queen correspondingly early in the season.

Offer No. 25.

For \$1.00 we will send GLEANINGS one year and a Clark smoker, postage 20 cents extra. Or, for \$1.25 we will send the Cornell smoker, postage 25 cents extra.

Offer No. 26.

For \$1.75 we will send GLEANINGS one year and our cyclopedia on bees, the A B C of Bee-Culture, of 475 pages.

Old as well as new subscribers may take advantage of these several offers, but all arrears or back subscriptions must FIRST be paid at \$1.00 a year. Refer to these offers by number to avoid mistakes.

The Bee-Keeper's Guide:

Or. Manual of the Apiary.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year.

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street,

CHICAGO, ILL.

Long-Tongued Bees

ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers (with \$4.00.)

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation—"first come, first served"—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipt, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

26 cents Cash
paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 26 cents a pound—CASH—for best yellow, upon its receipt, or 28 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO.

Best
White

Alfalfa or Basswood Extracted Honey

ALL IN 60-POUND TIN CANS.

ALFALFA
HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD
HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are box.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

THE OLDEST BEE-PAPER IN AMERICA

41st YEAR.

CHICAGO, ILL., MARCH 7, 1901.

No. 10.

Editorial.

The National Convention Report is omitted this week on account of more copy not being received in time from the secretary. We regret this second break in the long "continued story," as we desire to complete it as soon as possible.

A Glucose Test.—Editor E. R. Root said at the Wisconsin convention that adding an equal amount of wood-alcohol to honey, stirring well, and then letting it stand say ten minutes, is a good test for glucose in honey. If adulterated the compound would show a milky appearance, and remain clear if pure. This is a simple test, but we presume the wood-alcohol must be absolutely pure itself to start with.

Bee-Keeping at the Pan-American.—At the last Ontario County (N. Y.) Bee-Keepers' convention, Mr. O. L. Hershiser, superintendent of the apianian exhibit at the Pan-American Exposition, said that it was proposed to have a commodious building for the accommodation of bee-keepers; that bees alive were to be exhibited in regular yards as kept in different lands; and also that there would be shown articles from bakeries in which honey is used as an ingredient. The New York bee-keepers will be allowed to exhibit at least 5,000 pounds of honey, about equally divided between comb and extracted. The extracted is wanted in bulk, the State to furnish the packages in which it is to be exhibited. The State will also furnish the cases for the comb honey. All bee-keepers in New York, who have any honey suitable for exhibition, should address Mr. Hershiser. He will buy the honey outright, which, however, he will not do until next season, when the new crop comes in. No exhibitor will have to pay any freight charges. On request the honey will be returned to the exhibitor, or such disposition made of it as he may desire. Mr. F. Greiner furnishes this information for the American Bee-Keeper.

Big Yields of Honey. The Twentieth Century Farmer has been telling a whopper on the 19th century bee-keeping. Here is what it publisheth recently:

CYPRANS HOLD WORLD'S RECORD.

The next breed of bees imported came from the island of Cyprus. They are called Cyprans, a name not always used for bees. The Cyprans hold the world's record for the

amount of honey gathered by one colony in a single season. Mr. Doolittle, of New York State, a well known apiarist, took 1,000 pounds of extracted honey from one colony of Cypran bees one year. They have one serious fault—they are very nervous, and will defend their stores of honey to the death. They can not be subdued by smoke. When aroused the only way to conquer them is with a mild dose of chloroform. On account of their disposition they have not become popular.

Upon receipt of the Farmer containing the above paragraph, we clip it out and sent it to Mr. Doolittle, to show him what was being credited to him. And here is what Mr. D. says about it:

The above reminds me of the "man who puked up three black crows," of ancient time, while the truth was that "he threw up something as black as a crow, and told his neighbors so."

My greatest yield of extracted honey from a single colony of bees was in 1877, when one colony gave me the large yield of 566 pounds, besides producing enough to winter on—or about 35 pounds more. So that the total gathered by this colony was not far from 600 pounds, all told; that is, above what they consumed while gathering, or during the summer months. But this was before any Cypran bees were imported into this country, the bees doing the gathering of this 600 pounds being those best of all bees, *all things considered*—the Italians.

But this record of 566 pounds has been outdone several times. E. Gallup, while in Iowa, went considerably above 1,000, and P. H. Elwood, of this State, produced 640 pounds from one colony, if I am correct; while a Texas bee-keeper obtained 1,000 pounds, or a little over, from a single colony in the spring and its increase. This latter I have spoken of in print several times, always crediting the matter to the State of Texas. It would now appear that it has grown, like the crow story, till I myself produced the 1,000-pound yield, and did it with Cypran bees. But the Cypran part is wholly "manufactured," for, if I am right, this 1,000-pound yield was produced before any Cypran bees ever came to this country.

G. M. DOOLITTLE.

Omondaga Co., N. Y., Feb. 20.

That "Utterly Glorious Victory" won down in New York State last December grows more glorious all the time. Editor Root, in *Gleanings in Bee-Culture*, has a paragraph editorial with this quoted heading, "But 'Twas a Glorious Victory." Then right under it he gives the following from Josh Billings:

"Sun people that go to law for dammages sometimes get more than tha want."

After that comes this paragraph referring to the final settlement of the Uter vs. I Uter suit:

Just as this form is going to press I have received information that the plaintiff, or, as he is called, Fruitman Uter, has decided not to carry his case to a higher court, and he has settled by paying all the costs, which can hardly be less than \$500 or \$600. Thanks to the National Bee-Keepers' Association, the defense was so strong that the other side

knew there was absolutely no show for them. We met the enemy, and whipt him so hard that he knew there would be nothing left of him if he attempted to put up another fight. "Be well, Hiy, hup, hurrah for the Association!" Such a victory ought to appeal to every one of our subscribers who is not a member. Send in a dollar to General Manager Secor, Forest City, Iowa, and have a hand in this glorious work. There are more battles to fight, and we need your help, and—you may need ours.

Yes, Manager Secor ought to be kept busy now taking in the membership dollars. Surely, every bee-keeper should desire to belong to an organization that does such effective work.

If it is more convenient for the readers of the American Bee Journal to send their membership dues to this office, we will be glad to receive them and forward to Mr. Secor. We would like to see every one of our subscribers get into the National Bee-Keepers' Association. You can't help in a better way for the uplifting and defense of bee-culture.

The Production of Comb Honey.—Mr. F. Greiner reports in the American Bee-Keeper some notes from the Ontario County (N. Y.) Bee-Keepers' convention held last Dec. 13th and 14th. Referring to an address by W. Z. Hutchinson, he gives the following important point:

As soon as it is advisable to put on the honey-boxes or supers, give a super full of drawn comb. This will keep the honey out of the brood-chamber, and start the bees right. Empty sections, or such filled with foundation, do not fill the bill here. When the bees once get in the habit of storing their honey above, they are apt to continue thus throughout the season; when they form a habit of filling the brood-chamber with honey at the beginning of the season, they then are slow to enter the sections any time after. Mr. Hutchinson had observed that by giving supers full of drawn comb a case of honey was gained above what other equally as good colonies had made supplied with empty sections.

The swarms are treated according to the Heddon plan. Mr. Hutchinson had done a good deal of experimenting with swarms, buying them alternately on combs, foundation, and starters. The combs always gave the poorest results with him, and the foundation, aside from insuring perfect combs, proved a total loss. No young swarm is allowed more than five Langstroth frames, or one section of the Heddon hive. Contraction is practiced only on the swarms.

He has come to the conclusion that it is not always profitable to supply the bees with foundation. During a good deal of the season wax is produced anyhow, and if there is no opportunity to use it somewhere a large portion of it is lost. And, after all, he expresses his opinion that good, straight worker-combs were not too dear at the expense of the foundation.

A Looking-Glass placed before the hive-entrance is advised in the Leipzig *Bienenzeitung*, to scare away robber-bees. Perhaps it is thought that if the robbers could "see themselves as others see them," they'd "quit their meanness."

Contributed Articles.

A Successful Roof-Apiary in Chicago.

BY G. E. PURPLE.

TO relate my experience in keeping bees in the city, and how the idea occurred to me to keep them on the roof, I will have to go back a few years.

Like a great many others, my boyhood days were spent on a farm. When a boy 16 years old my father took some bees to keep on shares. It was not long before an interest in the little creatures was aroused in me, and I became quite a student of their ways, studying them as best I could while using a box-hive. After keeping them about two years in box-hives, having the usual failures one has when he works with them blind (one may say), I secured a copy of the "A B C of Bee-Culture." I began reading it and could not bear to drop it until I had read and reread it all thru, and from that day to the present time my enthusiasm has not abated. Not being blest with an overabundance of this world's wealth, I made hives and frames, and by the next season I had all the bees in movable-frame hives. I had six or eight colonies at the time.

Let me say here that before this we had returned to the original owner his share of the bees, so all we had then were our own.

The next two seasons were very favorable ones, and by the end of the second we had 30 or more colonies and succeeded in getting over 2,000 pounds of honey from 20 colonies, spring count—an unheard of amount in that country (northwestern Missouri).

The next three or four years were either entire failures or only a very little surplus. Having a very good position offered me in Minneapolis, I concluded to accept it, and leave the farm and bees to father's care. Father all this time had left the care of the bees entirely to me, and when the responsibility fell to him he was little prepared for it, and, as a consequence, the bees were more or less neglected, and gradually dwindled.

During my stay in Minneapolis I made the acquaintance of persons who kept bees, and we spent many an hour talking over our experiences, and enjoying ourselves as only enthusiasts can.

Owing to the financial disturbances of 1893, I found it necessary to change my residence from Minneapolis to Chicago, and have lived here since. While riding home from work one evening I saw a man sitting opposite me in the car reading the "old reliable" American Bee Journal. Of course I knew he was a bee-keeper, and knowing all bee-keepers are jolly good fellows, I ventured to speak to him, and he proved to be our friend Mr. Mead. I afterwards called on him, and we together examined his bees. I learned they did not disturb his neighbors, and that there were many nectar-yielding plants in the vicinity. That call revived in me the "bee-fever" again, and I determined to get one or two colonies as soon as I could find a place to keep them.

Soon after that I moved farther out, and while on the roof one day I thought it a capital place to keep bees, and the next spring I sent down home for one colony, and tried it. The colony father sent was not a very good one, and I bought two frames of brood and a queen from Mr. Mead to build them up. They did far better than I expected, producing over 150 pounds of extracted honey (borrowed the extractor) that season. The bees wintered well on the roof, packed in planer-shavings, and the next spring I sent for all there were left on the farm—only four, and one was dead when it reached me (starved out). So I started with four good, strong colonies. That summer they increased to seven, and I got an average of 150 pounds per colony.

In the fall I moved to the present location, and the following winter (1898-'99) was very severe on the bees. The long-continued cold weather prevented their moving to their stores, and one colony died with plenty of honey in the hive. Only two came thru strong, and four were very light. We had a very early spring, and I never before saw bees build up so rapidly, so by the time the honey-flow came on, they were all good and strong. But it was the first season I ever had reason to complain of my luck: I lost queen after queen, both old and young, and only increased to nine colonies, these producing over 900 pounds of honey.

The next winter, not having them fixed properly, I lost two, and doubled others up. I started with five of my own, and bought 10 more, increased to 21, and produced nearly 3200 pounds of extracted honey. The engraving shows the apiary one Saturday afternoon in August, when Editor York called with his photographer, and took our pictures after we had (as an old friend says) "climbed Jacob's ladder to the bee-heaven." (See first page).

When one keeps only a few bees, more for the pleasure than the profit, and does the work connected with them at odd times, he can keep close watch of each individual colony, and get better results in proportion to the numbers than with a large apiary, and they will amply repay him for the small outlay at the start, and for the time spent in taking care of them.

The roof as a place to keep bees has its advantages as well as disadvantages. Things in its favor are that the bees are up out of the way, and there is no fear of their disturbing anyone. (I have never heard any complaints against mine). The roof being nearly level, and covered with clean gravel, there is nothing to hinder the bees, and when they swarm it is easy to find the queen. (I clip all my queens.) While the drawbacks are, getting everything up there, as well as getting the honey down to extract and handle, and some days the wind blows so hard that the bees can scarcely get to the hives at all. Many think it quite a novelty, but the novelty has worn off with me, and I derive a great deal of pleasure as well as profit from my bees, tho kept on the roof of a modern flat-building in a big city.

Feb. 1, 1901.

[We might add to the foregoing that Mr. Purple's honey source is principally sweet clover. His apiary is located about five miles west of the Lake, and is a very neat one. He reaches the roof thru an opening directly above one end of the porch at the rear of the third flat in which he lives.

Mr. Purple is a very pleasant gentleman to meet, and thoroughly understands bee-keeping. He would be successful almost anywhere with bees, provided there was plenty of nectar for them to gather.

We spent a delightful hour at his roof-apiary, and were surprised to see how abundantly the bees had rewarded his efforts during the summer.—EDITOR.]

A Review of "A B C of Bee-Culture."

BY PROF. A. J. COOK.

IT has been a pleasure to review "Dadant's Langstroth" and "Cowan's Honey-Bee," as there is so much to commend and so little to criticize in these volumes, each of which is a credit to our nineteenth century bee-culture. They are books which deserve to live and which will live. I come to the pleasant duty of reviewing "A B C of Bee-Culture" with no less of gratification. Without doubt this book has exerted a wider influence upon the bee-keeping world than any others ever written. Even its rivals can only be joyous in its extensive sale, as they know that wherever it goes it goes to help and to bless. I am the more pleased to do this as I have received several letters thanking me for the reviews of the other books. These reviews certainly call attention to mooted questions and will be almost certain to incite criticisms. I shall criticize no point except in such cases as I have good reason to believe that there is an error, but it is quite possible that in some cases I may be in the wrong.

Page 2.—Mr. Root says, "Candidly, I don't know any better way to prevent second swarms than to watch carefully when they are to be expected and then chase after them, climb tree, etc., until they are gotten safely into the hive." I believe that the experienced bee-keeper will rarely be troubled with second swarms. One is enough for the best results, and some of the many ways will, and should, be used to prevent the second swarms. I think the way first suggested by Mr. Heddon is certainly the best. The principle of this is in placing the new swarm close beside the parent colony, and the day before the second swarm would be expected remove the old hive to another part of the apiary. Of course, the older bees will go back to the old location, to join and strengthen the swarm, while the old colony will be so thinned out that very rarely a second swarm will

issue. I used this method for years and with no failure, so far as I know.

Page 6—Is not Mr. Root a little too enthusiastic regarding alfalfa honey, when he says "the quality of alfalfa honey is probably superior to anything that the world has ever produced from any other source"? I claim to be something of a judge of honey, and I think alfalfa is no better than clover, linden, sage, and I think I might find even others quite equal to it.

Page 7—In California it does not take three years to get the best yield from alfalfa. In fact, we often get a maximum yield the very first year in the later cuttings. Alfalfa is a wonderful crop. I often say that I think I would rather have a good alfalfa field than an orange orchard. I have known several cases where seven cuttings have been made in a year, and it is not uncommon to secure two tons per acre from a cutting. In this same connection, Mr. Root hints that there is so much sweet in alfalfa that the bees even gather (sic) from the dry hay. This is putting it altogether too strong. Still I do not think that too much can be said in favor of alfalfa for it is a marvelous crop.

Page 12—Mr. Root says that digestion is the separation of the nutrient part of the food from the non-nutrient, and the conversion of the nutrient into a liquid fit to mingle with the blood and thus nourish the body of the insect. This is given as a question but he was not happy in his selection of authority. Digestion is simply the fitting of the food to be absorbed. I tell my class that "digestion is rendering the food osmotic." Many authors say that digestion is merely to dissolve the food. This is not a good definition. Some of the food that is already dissolved, like blood albumen and cane-sugar, must be digested before it can be absorbed from the stomach into the blood. That is before it is osmotic. Absorption, not digestion, does the work of separation. One other of our bee-books makes this same mistake.

Page 10—In speaking of the urinary tubes appended to the stomach, Mr. Root calls them the "malpighian tubes." It should be "malpighian," as they were named from their discoverer, Malpighi, a distinguished Italian physiologist and microscopist. Mr. Root says further of these tubes, "It is not certain what their office is, but it is thought that they are the urinary organs." This is no longer true as urea, etc., have been found in these vessels, so we now know that they function as kidneys.

Page 44—In speaking of the advantage of black bees, from the fact that they can be shaken off the comb so easily, Mr. Root says, "For that reason alone some prefer them, or hybrids, to pure Italians, which can hardly be shaken off." I have very little trouble to fell at one shake every Italian bee from the comb if the latter fully fills the frame. This requires a peculiarly sharp jerk which every apiarist should learn to give. He should also learn to keep the frame perfectly vertical else the comb may follow after the bees, which is about as annoying a thing as can happen in the apiary. I should make this characteristic a count against the black bee and in favor of the Italian. As our best men love their homes so well that they always stick to them if possible, so I prefer the bees that endeavor to stick by their comb.

Page 45—Mr. Benton did not spend the best years of his life in the jungles of India, in search of new bees. Mr. Benton was in India only a few days. I think he was only a few days in Ceylon, where he secured *Apis dorsata*.

Page 47—It is unfortunate that our authors use the term worm and grub as synonymous with larva. I know this is commonly done but it is wrong, and how shall we correct errors unless our authors avoid them? Entomologists confine the term grub to the larva of beetles, while worms are not insects at all. Worms, as instanced in the angleworm, never have any legs at all, and look essentially the same from first to last except for size. All mature insects have legs and are very different from the larva, or insect, just after hatching. Why not always speak of the immature bees as larva and be correct?

Page 49—It is here stated that it is supposed that this larval food is pollen and honey, partially digested by the young or nursing bee. I with others have positively proved that this larval food is perfectly digested pollen, with or without the addition of honey. Planta has shown that the drone-larva have mix with this food toward the last a little undigested pollen.

Page 50—In speaking of viper's bugloss (*Echium vulgare*), Mr. Root calls it blue thistle, and speaks of the danger of introducing the seed. This belongs to the borage

family and is no thistle at all. This name should never be used. It is like borage in being no serious pest.

Page 98—Are the drones from the laying worker eggs smaller than those from the queen's eggs? I am sure this is not always true. I think Mr. Root right in questioning the fertility of such drones, tho I am of the opinion that they are functionally perfect. I arrive, of course, at this judgment from a study of their anatomy.

Page 101. It is very doubtful, indeed, that unimpregnated eggs will ever produce workers. That queens with imperfect wings sometimes lay eggs that produce worker-bees would seem to prove that occasionally a queen may mate in the hive. I feel quite positive that I once had a queen that was so mated. I can explain the case in no other way. Yet it is so exceptional that I still feel a doubt in the matter. I think in writing we should use the word fecundate or impregnate rather than fertilize, as we also better use the word pollinate instead of fertilize. Let us reserve the word fertile to indicate that the male or female is functionally perfect or sexually perfect.

Page 126—A case is given where night work with bees was carried on successfully. I occasionally practiced night working with bees where it was imperative, but I did not like it and would not recommend it except in extreme cases. The bees have such a way of crawling around and are not discriminating. Were I to work at night I should want a string around my "pantlegs," as also my wrists, and should desire my bee veil tucked well in at the neck. Our author recommends this night work to prevent robbing. The beebent and other suggestions given in all our best bee-books are, I think, greatly to be preferred.

Page 126—"You could feed white sugar so as to produce very nice looking honey, but it would be sugar syrup in honeycomb after all, as you would find to your sorrow if you should attempt to sell it as honey." This is simply not true, as one experiment will satisfy anyone if he will but try it. I believe in telling the truth even if it confronts the prejudices of the whole bee-fraternity. Mr. Abbott at the last National convention stated and reiterated this untruth. If Mr. Abbott will feed his bees pure granulated sugar syrup and then taste of the product, he will find that it is certainly honey and not sugar syrup. It surely will lack any aroma which might be secured in the nectar of flowers, but it will have decidedly the taste of honey, and will be preferred by many to any other kind of honey, as I have proved more than once. Yet it will rarely if ever pay to do this even if there were no prejudice against it, and in view of the prejudice it would certainly be unwise. Let us talk, however, of its nonprofitableness, and of its unwisdom, and not state what we can all so easily prove is not the truth. I was brought up to believe that untruths never pay, and I have never yet seen reason to believe otherwise.

Page 129—I have always wondered at the statements we so frequently see of bees expelling water from the honey while on the wing. I never saw it and don't believe they ever do it. We have so many reports that there certainly must be some ground for the opinion. If a fine mist does escape from the bee, it is surely one of two things—either excreta from the intestines, or perspiration from the bee. The bees exercise very severely and must of necessity cool off. This must be done thru perspiration. This perspiration must occur in the breathing tubes as the thick chitinous crust of the bee's body would preclude much if any sweating from the exterior surface. I have no doubt that much evaporation of moisture escapes from the trachea of the bees when the latter are hard at work in very hot weather. That this might descend in a mist is possible. I should like, however, to see it.

Page 142—Our author speaks of honey from the nectar of fruit-blossoms as of poor quality. I would like to hear from others on this subject. I was once so happy as to get some unmixt apple-blossom honey. I thought I had never tasted any so excellent. Others to whom I gave this were equally enthusiastic.

Page 144—I have often been puzzled, as has Mr. Root, in the varying opinion among fruit-growers as to the value of bees in the work of pollination of fruit-blossoms. I know positively that some varieties of fruit are at times entirely fertile to their own pollen, and again utterly sterile to the same. The vigor of the tree must play no small part in this matter. Yet no fact in pomology is better attested than is the necessity of bees in or near the orchard if we are to secure the maximum fruitage.

The Premiums offered this week are well worth working for. Look at them.

Management for Producing Extracted Honey.

BY C. DAVENPORT.

FOR the last seven or eight years I have run from 30 to 40 colonies for extracted honey, and intend this season to increase the number to over 100, and I will describe the plan or method on which they will be run, and tho this method might not answer for some localities, it is the one that will work here, I believe, and secure the most surplus with the least work.

While it is generally claimed and conceded that it requires less work and skill to produce extracted than comb honey, I have not found this to be altogether so. If I had for the last few years I should have been producing extracted in a much larger way, and would do so now. The first season I ran a number of colonies for our product in the liquid form, it seemed to me that it required fully as much, if not more, work as well as skill to produce a first-class article of extracted honey, as it did fancy comb honey. But I have learned enough about this branch of our pursuit since, so that I can now produce extracted with considerable less work than comb.

Now the question may occur to some, why I started and kept on producing extracted honey, if, with me, it required as much work and skill as it did to produce comb honey. There were a number of reasons for this, and two of the principal ones I will explain. One was that there was a local demand for extracted honey, at a better price accordingly than there was for comb honey. I had, and have at present, a still larger number of customers who prefer honey in the extracted form, many of them preferring it because it is cheaper—in fact, I have a good many customers who use a large amount of extracted honey every year, and pay a good price for it, compared with the price of comb honey, who would buy but very little if any comb honey, because they could not or at least believe they could not—afford to. Others actually like it better in the extracted form, and again some who are very fond of candied extracted honey care very little about comb honey. Personally, I much prefer it in this form to comb honey.

I used to extract a large amount of honey from the brood-chambers late in the fall, then feed sugar syrup for winter stores. At that time there was a good profit in doing this, and the bees seemed to winter fully as well on granulated sugar, as it was then made, as on natural stores, and the honey thus obtained, tho it might be somewhat mixt, was always thick and rich. But the price of our product dropt so low that there was no longer profit in producing extracted honey in this manner, tho I had a trade for it already worked up—a trade that, as I have explained, would not take comb honey in place of extracted.

Another, and more important reason, was that about that time (and I have seen no reason since to change my opinion) I became convinced that more money could be made from a large yard by running part of the colonies for extracted honey, for here a range may be overstocked during the forepart and latter part of the season, and still not have enough bees to gather what nectar there is during clover and basswood bloom. This is not the case every season, but on an average it will hold true two seasons out of three, and a colony that is being run for extracted honey can gather considerably more nectar than one being run for comb honey, for these reasons: A larger number of colonies can be profitably kept in one yard if part of them are run for extracted, than could be done if they were all run for either comb or extracted honey. After carefully repeated experiments, some of which I have described in these columns, I know, if I know anything about bees at all, that more extracted honey can be secured here if the queen is confined by zinc to the lower story of a hive not larger than the 10-frame. The reason for this is, that with a larger brood-nest an immense force of bees are reared out of season, to be producers, but are, instead, consumers. I know that this matter of rearing bees out of season has been ridiculed by some, but here it is a more important matter—one that to ignore may mean the loss of a number of thousand pounds of surplus honey with a large yard, each season. I am aware that this is a strong assertion to make, and that it is likely to be disputed by many able ones in our ranks, but it should be borne in mind that I make this claim only for my own locality, and for others where the flows are similar to what we have here, relatively to the season.

It may be of interest to the newer readers of this journal, for me very briefly to go over the experiments I made to find out whether it was more profitable to allow

more than one story for a brood-nest. These experiments extended over a number of seasons, with slightly varying results, owing to the varying conditions of the seasons, as well as that of the bees. But without any exception they all showed that a brood-nest here could be so large that it would reduce the amount of surplus extracted honey that could be obtained; besides, these large brood-nests, especially the unlimited ones, entailed much more work to get what surplus there was, and to reduce or get the bees into one story again for winter.

My method was, each spring, to select 30 or 40 colonies as nearly equal in strength as possible, and divide them into lots of 10 each. The queen in one lot would be confined by zinc to one story; those in the second lot would be allowed two stories for a brood-nest; while the queens in the third lot were allowed their will in 3 or 4 stories. Some lots were in 10-frame hives and some in 8-frame, and, so far as surplus honey was concerned, these two sizes of frame made but little difference either way. But with the plan I now practice, there is considerably more swarming where the queens are allowed 10 frames than there is when they have only 8 for a brood-nest. When the queens are allowed two brood-chambers there will be here, in a good season, about half of them that will swarm, and some seasons as large a percent of swarming will take place when the queens are confined to 10 frames; but with only 8 frames for a brood-nest the swarming will not be over 10 percent—it has been less with me the past two seasons. It is true that both seasons were poor ones, still there was enough honey gathered so that nearly 30 percent of the colonies that had 10 and 16 frames for a brood-nest swarmed, or tried to do so.

Southern Minnesota.

To be continued.

Longer Tongues and Larger Bees, Etc.

BY ADRIAN GETAZ.

BEES with longer tongues is the topic of the day. Measure the length of the tongues of the different colonies of bees and select for breeding those with the longest-tongued bees, if I can use that expression.

Well, to begin with, I doubt about the exactness of the measurements given by Mr. Ernest Root and a few other experimenters. It seems to me that the difference between the tongues measured is too great. There is hardly any difference in the size of the bees and in the different organs and parts of them; and I don't see how the tongues could make such striking exceptions, the measurements varying between 13-100 and 23-100 of an inch. The tongue of a bee is very near as elastic as a man's tongue. How could you measure exactly the length of a man's tongue which can change its length, width and shape in all sorts of different ways? And it is nearly so with bee-tongues.

The method employed to measure them, is to chloroform the "subjects," which makes them extend their tongues, and measure them with calipers. But what proof have we that they all extend their tongues to the same extent? None at all.

Again, there is a considerable difference between the length of tongues of the different bees of a colony (when measured by the above-described process), and even admitting that the measurements are correct we can measure only a few bees—say 20 or even 30 out of at least four or five thousand bees of a colony. We may have measured some of the shortest in one colony and some of the longest in another, and failed to reach the proper average length, or rather maximum length, for this would be the important item to obtain.

I do not say that this method of measurement should be discarded, but I think necessary to have some indirect way to check it, and ascertain to what depth the bees of each colony can reach for the honey in the flowers. For this I think an instrument as here represented would be the best. It is simply a trough 4 or 5 inches long and not more than $\frac{1}{4}$ -inch wide inside. The top is made of wire-cloth thru which the bees can suck the syrup. The depth is from $\frac{1}{4}$ of an inch at one end to nothing at the other, forming an incline. A scale is marked on the bottom dividing it by transverse marks in 25 parts graduated from 0 to 25, commencing at the end where the depth is nothing. To use the instrument, fill it with syrup or thin honey thru the wire-cloth. Place it in an empty super on the top of the brood-nest or the super that may be already there, being sure that it is level. This can be easily done by placing it so that the syrup comes even with the wire-cloth over the

whole surface. When the bees have taken all that they can, notice (without disturbing the instrument) to which division the syrup reaches. If it reaches, for instance, to the 17th mark, it shows that the length of tongue of the bees, or rather the distance from the wire-cloth to the level of the syrup, is 17-100 of an inch, and since the 25th division corresponds to a depth of $\frac{1}{4}$ of an inch that is 25-100.

This instrument will give a depth or length of tongue rather too long, as a portion of the bee's head above the tongue may go thru the wire-cloth. From a practical standpoint, it is immaterial whether we get the exact length or not—what we need to know is the comparative length, or in other words, which bees can reach the deepest. If several instruments are used, and the results to be compared, it will be necessary to use the same kind of wire-cloth on all, for the reason that a greater part of the bees' heads

could go thru a larger wire mesh and enable them to reach deeper. The instrument should be constructed accurately, waxed or paraffined so as to prevent swelling of the wood and possible distortion. Care should be taken that the wire-cloth should lie evenly all over, and for that reason the instrument should not be wider than $\frac{1}{4}$ of an inch, otherwise it would be difficult to prevent the cloth from bulging in places. When it comes to measure to a precision of 1-100 of an inch, the instruments used must be accurately and carefully made.

LARGER BEES FOR LONGER TONGUES.

All other things being equal the largest bees should have the longest tongues. And to have the longest tongues possible, it will be necessary to have the largest bees possible. In fact, the main argument presented in favor of a larger race of bees is their presumed ability, thru a longer tongue, to reach the nectar of flowers too deep for our present race of bees, especially the red clover.

There would be another advantage in having larger bees. That is, less time lost in going to and coming from the fields. Suppose you had a pile of materials to remove—say 2,000 pounds—and want it carried to a distance of 500 yards. If you employ a man able to carry only 50 pounds at a time he will have to make 40 trips—that is, walk a total distance of 20,000 yards. If you take a man able to carry 100 pounds at a time, he will have to make only 20 trips, therefore to walk only 10,000 yards. It may take him as much time to load and unload his 20 loads as it takes the smaller man to load and unload his 40 loads, and he may not walk any faster, but even then, he would be ahead of the time necessary to walk thru 10,000 yards. So it would be with larger bees—they certainly would lose less time in going and coming.

EFFECT OF COMB FOUNDATION.

A few years ago the question was asked, "Has the size of the foundation cells any influence on the size of the bees reared in them?" To my surprise nearly all the "wise men" answered, "No, none at all." And yet it is self-evident that no bee can be larger than the cell in which she has been reared, for the simple reason that all her growth is done when she emerges, and her skeleton already formed and too hard to expand any. The abdomen and other soft parts can and do expand some after the emergence.

All the above-mentioned "wise men" knew good and well, that the drones reared in worker-cells are much smaller than those reared in larger cells.

Before foundation was used there was quite a difference between the different races of bees in regard to size. There was a race of black or brown bees in Holland much smaller than the common German bees. The Carniolans were distinguished by their large size. Among other figures we have some of Cheshire giving the weight of 20 Cyprian bees at 28 grams and of 20 Carniolans at 40 grams. We don't hear any more about a difference of size, now. Why so? Just because foundation of a universal size is

universally used—5 cells to the inch—and with a uniform size of cells has come a universal size of bees.

The first step will be to use a larger size of cells. But that is not sufficient. The size of bees will not increase at once, simply by giving larger cells. It will be necessary to select the queens giving the largest bees, and keep on breeding for the largest all the time. One drawback will be that with a larger size of cells there may be an over-production of drones. The only way to prevent it would be to increase the size of cells, at first of only a small fraction, and later, when the new race is established, make another increase.

Several years ago, a distinguished French apiarist, Mr. Drory, gave a number of queens only drone foundation. A number of them reared worker bees in those sheets, but some others only drones. I have not the details of the experiment. Judging by what has been done with horses, dogs, fowls, etc., we might think it possible (and perhaps it is) to create a race of bees even larger than the Apis Dorsata. We shall name it (if it comes) "Apis americana." Knux Co., Tenn.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—Editor.)

Plan for Comb Honey and Increase.

1. What do you think of the following proposed plan for comb honey and increase?

The staple honey-plants for this locality are the wild red-raspberry, and buckwheat. Build colonies up as strong as possible even to the point of swarming, for the raspberry bloom, then divide by taking the queen, and say three frames of sealed brood, from the parent hive, place them in the new hive with a couple of frames of foundation, and place the new hive on the stand of the old one, removing it to a new stand and in the course of 24 hours introduce a Carniolan queen. We have here forage for bees at all seasons; basswood is not sure for surplus. The present bees are Italians, which we mean to keep up, the only object in putting in the Carniolan being the *reputed* prolificness.

MICHIGAN.

ANSWER.—Your plan and your surroundings are so much out of the line of my experience that I do not feel very competent to answer. However, I am not very much afraid of doing harm, for sharp eyes are ever on the watch to correct what may be wrong. For those sharp eyes I am thankful, for I well know that eyes may be very sharp and at the same time very kindly.

Your plan is evidently intended to obviate swarming, and yet I am a little afraid it might not be successful in general. A more severe depletion might be needed, and I should advise trying at least some colonies by leaving with the queen on the old stand not more than one frame of brood, filling up with frames of foundation, and brushing the bees off about half the frames removed. Then two or three days later take away their remaining old frame of brood.

If you have never tried Carniolans, it might be well for you to try giving them to only part, so as to compare their work with that of your other bees.

A Beginner's Questions.

1. Where can I find the queen-cells? Also tell me other things which I, as a beginner, do not know.

2. Is buckwheat a good honey-plant?

3. I hope soon to be able to purchase "A B C of Bee Culture," or "Langstroth on the Honey-Bee." Which is the better for me?

MISSOURI.

ANSWERS.—1. From the way in which you ask the question, it is possible that you think there is a cell in the hive that the queen keeps for her own, perhaps retiring to that cell every night to go to sleep. So far from this being the case, it is true that after the young queen emerges from her

cell she never enters it again, and it is not a great while after she leaves it until the workers tear it down all but the base or enough to make a concave hemisphere. If you look into a hive at this time of the year, it is not likely that you will find a queen-cell in it, but you will be likely to find quite a number of cell-cups, some of them the remains of queen-cells from which queens have issued, and some of them cups that the workers have started and never finished, and most of them they never will finish. If you look into a hive at the time a first swarm issues you will find 5, 10, 20, or perhaps more queen-cells with young queens in them, and they may be in any part of the hive. Generally they will be found near an edge of a comb, possibly right among the worker-brood near the center of a comb where there happens to be a hole or an irregularity. Sometimes you may find a queen-cell not on the comb at all, but built directly on the wood of the end-bar, but this is very rare.

You must excuse me from attempting to tell you all the other things that you as a beginner do not know, that is, if the list of unknown things is as long as my list was when I was a beginner. It would take many pages of this journal to contain the answers to all the questions I had, but most of the desired information can be obtained from the excellent text-books we now have.

2. Buckwheat is one of the best honey-plants. It does not yield the best honey, for the honey is very dark, and most persons do not like it so well as honey of milder flavor, and yet some prefer buckwheat honey to any other. It is, however, a somewhat fickle yielder, one year yielding an abundant harvest and the next yielding nothing.

3. If you get either you will have a treasure, and will find in it so many good things that you will wish you had the other also, with Prof. Cook's excellent work added.

Introducing a Queen to a Colony that Has Just Swarmed.

I would like to know, just after a swarm issues, how to give the old or mother colony a laying queen.

WISCONSIN.

ANSWER.—Give the queen in an introducing-cage, and there may be no trouble without any further attention. It will be safer, however, to destroy all queen-cells in the hive.

Putting Bees Out of the Cellar at Night.

Is there any objection to putting bees out of the cellar at night?

WISCONSIN.

ANSWER.—There is probably no difference between putting bees out at night and putting them out the following day. That is, if you are sure you will put them out tomorrow morning, you may as well put them out to-night. But you can not always be entirely sure at night that you will want to put them out in the morning. For the weather is sometimes so changeable that between night and morning the temperature may sink so many degrees that it will not be safe to have the bees out. When bees have been in the cellar all winter and are put out-doors, they are not as prudent as they might be, and will fly out in weather when large numbers of them will be chilled and be lost. If you could be sure of good weather the next day, it would be all right to take out bees at night, but on the whole it is more prudent to take them out when you know they can fly with safety within ten minutes of being taken out.

Uniting Colonies and Introducing Queens.

1. I have some colonies which I wish to unite. When do you consider the best time in the spring for doing it?

2. Which plan is the best?

3. Would it be advisable to introduce a new queen at the same time?

BRITISH COLUMBIA.

ANSWERS.—1. If you intend to unite colonies in the spring, it may be safely concluded that it is because the colonies are not strong enough single. If you have two colonies, each having bees enough to cover two frames of brood, they ought when united to be able to cover at least a little more than four frames of brood. At all events, when the two are united you will have six frames of brood sooner than you would have done if you had kept the two separate. So you can easily see that you will gain nothing by wait-

ing, and the sooner the uniting is done the better. Unite before the bees begin to fly, and there will be less danger of the bees of the removed colony going back to the old place.

2. There is little danger of fighting if you alternate the frames with their adhering bees, first a frame from one hive then a frame from the other, and so on. If you unite before the spring flight, there is little danger of trouble if you simply put one set of combs in the hive beside the other. In any case, if you see any bees doubled up in the death struggle on the bottom-board after having been stung, or any other sign of fighting, give them smoke till they promise to be good, as Mr. Root says. If they get bad again, smoke them again.

3. Yes, you can introduce a queen at the time of uniting if you kill the other queens, altho on account of the greater difficulty of getting queens in spring, and the greater cost, very few queens are introduced in early spring.

Excellent Alfalfa Honey.

I have mailed you a sample of honey that I think to be first quality, and would like to have your opinion.

UTAH.

ANSWER.—I have no quarrel with you for calling it first-class. It is very white indeed, and altho very mild in flavor, like all alfalfa honey, what flavor there is is excellent.

Convention Proceedings.

Report of the South Dakota Convention.

BY E. F. ATWATER.

The annual convention of the South Dakota State Bee-Keepers' Association met at Vankton, Jan. 25, 1901. More than half the members were present, and all were very enthusiastic, considering the past poor honey season.

Many interesting points were brought out in the discussions; a short talk by Daniel Danielson, was especially interesting, his subject being "Migratory Bee-Keeping." Some years there was a good profit in moving bees from one locality to another; in other years it would be a loss, as the honey-crop can not be foretold. In moving bees they should have an abundance of ventilation, and the hauling should be done at night, when possible. Cold water soured down thru the hives helps to bring the bees thru in perfect condition, without loss of energy or numbers.

President Thos. Chantry called attention to the real necessity of maintaining our organization. Our association protects its members, as we have joined the National Bee-Keepers' Association in a body. If all the State bee-keepers' societies would join the National in a body it would be a great help to the National in its great work of fighting adulteration, and protecting the bee-keepers of this country. All the bee-keepers of the State should get in touch with the State association, as by so doing they get full protection from the National also. Many of our members have saved several times their membership fee, in buying their supplies thru the association.

A paper on foul brood—that most destructive of bee-diseases—was read by E. F. Atwater. By special request, the Rev. Dr. Matson, formerly of Ohio, spoke briefly on the "Home of the Honey-Bees," and of the members of the Root family. His address was very enjoyable.

E. F. Atwater was made Association foul-brood inspector for South Dakota.

At the evening session J. J. Duffack gave a report of the great National Bee-Keepers' Convention, at Chicago, bringing out very prominently the great need of a suitable National pure-food law.

A paper by Mr. R. A. Morgan, formerly an extensive Wisconsin bee-keeper, touched on the value of honey as a food, its wonderful keeping qualities as compared with butter and other foods, the causes and processes of swarming, and queen-rearing.

Mrs. John M. Downer spoke of the convention of the Horticultural Society, at Sioux Falls, S. D., and of the grow-

ing sentiment in favor of holding the bee-keepers' and horticulturalists' meetings at the same time and place.

In the question-box and answers, glass was decided to be the best package for retailing extracted honey. A point brought out that is not well understood by the general public is that practically all granulated honey is *pure*, and easily liquefied by gentle heat.

In regard to honey-plants, catnip was thought to yield very little; sweet clover is the great honey-plant for South Dakota. Fifteen acres of sweet clover supported 30 colonies, and each colony gave about 50 pounds of surplus honey. It was thought that 70 colonies might have given as large yield per colony, as 30 colonies did not seem able to work the entire field.

Increase by dividing was generally preferred for the experienced bee-keeper.

Attention was called to the good qualities of sweet clover hay, but horses and other stock must be taught to eat it, and it must be properly cured.

Thomas Chantry was elected president; J. M. Hobbs, vice-president; J. J. Duffack, general manager, and E. F. Atwater, secretary.

The committee on resolutions reported as follows:

Resolved, That the South Dakota State Bee-keepers' Association call the attention of all other State bee-keepers' societies, to the benefits of joining the National Bee-keepers' Association in a body, thus increasing the membership and power of the National Association.

E. F. ATWATER, Sec.

The Vermont Bee-keepers' Convention.

BY M. F. CRAM.

The 26th annual meeting of the Vermont Bee-keepers' Association was held in connection with the Vermont Horticultural Society, Dec. 5, and 6, 1900, at Brandon, under the auspices of the Brandon Grange, which furnished hall, lights and music.

The meeting was opened by Pres. R. H. Holmes, and prayer was offered by H. L. Leonard. The minutes of last meeting were read and approved. The Secretary's and Treasurer's reports were read and approved.

Pres. Holmes' address was delivered without notes, and as the secretary is not a shorthand reporter, he caught only some of the more important points. Mr. Holmes said that Vermont produced $1/33$ as much honey as California, where the honey is mostly extracted, but Vermont honey is mostly comb. What Vermont lacks in quantity she made up in quality. Vermont leads the country in quality of horses, butter, apples, sugar, etc. Addison County produced $2/3$ of all the honey in Vermont, but he thought honey could be produced in other places at a profit. The public were not informed in regard to the method of producing honey, but were learning. People have to learn to keep bees, the same as any other business, in order to make a success of it. There is no luxury that people like more than honey. Honey is something that would keep—it need not be sold until the producer is ready. Altho the last two seasons have been poor, bee-keepers are not discouraged. We should have better seasons soon. Eternal vigilance is the price of success. We are met to tell each other of our success and failure, and the points of interest in our pursuit.

A discussion followed on the peculiarities of the past two seasons. Mr. Leonard said Rutland County had had better seasons than some other counties, but the past two seasons had been very poor, 1899 being the poorest season without any exception for 50 years.

The past seven years have been poor for honey-production. Mr. Cram said that 1860 was the poorest season he ever knew—about every colony in Addison died.

Mr. Leonard had had seasons when his colonies averaged 100 pounds each, but they had not done so for the past seven years. We have made great strides in the management of bees in the last 50 years.

Mr. Larrabee spoke about the bees' building comb when the season is dry; also that the bees cap the comb more readily in dry seasons than in wet ones.

Mr. Crane said one class of flowers would produce honey one year, and the next year they would not, but some other would take their place. The past season was the best for 40 years, thru fruit or apple bloom.

Mr. Terrill from Lamolite County, said that bees did better last season than in 1899. He got no basswood honey tho it bloomed full.

M. F. Cram then gave his method of getting a crop of honey in a poor season, which was in reality the same as in

good ones. The first thing he did was in the month of July the year before, and that was to see that each colony was put, and kept, in such condition that it would have a hive well stocked with bees in September or the first of October. He could not let his bees swarm later than June and get good results from them the next season. There was generally a honey-flow some time in the season, and in his locality it was usually in June. He had his colonies strong early, or he "got left." His main honey-crop is from raspberries. He used a larger hive—(9 frames) about one foot square. We didn't very often lose any bees in winter, not more than one or two percent, but in the fall he had doubled up and had some empty combs. In the spring he has had some colonies so strong that they would occupy two hives in good shape—one empty hive on top of a strong colony. The queen would occupy both brood-chambers. He had one queen enter an empty brood-chamber and lay 11,000 eggs in three days. When some other colony swarmed he drove the bees all down out of the top brood-chamber, and then hived the new swarm into that, putting on sections, and also putting sections in the place of the removed brood-chamber, and both colonies would push things with vigor. He wintered his bees in the cellar with no upward ventilation, and didn't remove them from the cellar until they could gather pollen.

Mr. Crane said it was well for every one to study his locality, and be ready when the flow comes.

The chairman appointed the following committee on nominations: G. H. Terrill, A. J. Vail and Lewis Bascom.

QUESTION BOX.

QUES.—Can bees make comb out of sugar? ANS.—Yes.

QUES.—Is the honey as good for comb building one time as another? ANS.—Yes; but the temperature is not.

What is the difference between honeycomb and honeymoon? ANS.—Honeycomb is composed of a lot of small cells, and honeymoon is one big cell.

Does alsike clover produce honey the first season? ANS.—Not in sufficient quantities to produce surplus honey.

How are surplus combs stained?

Mr. Larrabee said they were stained by wet weather, also by using old comb where the bees had died.

Mr. Crane then spoke on trayed stain. It is caused by several things, one is using foundation to cap with; another cause is pollen. Sulphur will remove it. Propolis used to seal the combs could not be removed, but could be lightened in color. He had made a little tent or lean-to, and had used it for bleaching. It was 10x13 feet. He could bleach 1,050 sections at one time.

The committee on nominations reported as follows: president, J. E. Crane; secretary, M. F. Cram; treasurer, H. L. Leonard; vice-presidents, Orange County, T. H. Edson; Lamolite, E. K. Seaver; Chittenden, O. J. Lowrey; Rutland, V. N. Forbes; and Addison, L. O. Bascom.

All were elected.

Mr. Crane gave his paper on pickled brood, which the secretary failed to get, but the disease is not serious in Vermont.

Mr. Leonard then gave a talk on the loss of queens in mating. If separated far enough they would not be lost in a house apiary. If there is room to place one hive at every other place, it will help.

Mr. Holmes has a house apiary. He painted up and down the building 6 feet wide in red, white and blue, and lost 16 out of 26 queens. There was no difference in loss whether they were at the end or middle of the building.

Mr. Crane had changed the entrance and it had helped. He had noticed that if some object were placed near the hive it had helped about the loss in mating.

Mr. Leonard had trouble with bees leaving their hives and going in where there was a queen, they in the meantime being queenless.

Mr. Holmes had had swarms mix in his house apiary on the side of the building.

A vote of thanks was extended to the Brandon Grange for the use of the hall and for music.

The time and place for the next meeting were left with the secretary to confer with the secretary of the Horticultural Society, to meet as they could arrange.

M. F. CRAM, Sec.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription *a full year in advance*, we will mail you a Wood Binder free—if you will mention it.

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

THREE "WIVES" IN ONE HOUSE.

Of course we are Schmidten with desire to know how three queens to one colony are secured, page 71. Was the information withheld on purpose to make us cry for it? We can see that there are three stories and three entrances. I'll guess that the mid-story has zinc both above and below, and a partition across the middle. But then, but then; it's one thing to show us how to have three wives in one house without any quarreling, and quite another thing to prove that such an establishment is wise or profitable. I can see that a *queen-breeder* might like to have an excess of tested queens to draw upon.

WANTED—A NONTRUSTABLE HONEY CAN.

But, Mr. Aikin, I don't want to speak well of a honey-can that will burst unless we wait for the honey to candy before we ship it. Better we insist on a can that will carry liquid honey to market. First you know, we shall learn the art of keeping our honey liquid pretty much all the time. A non-trustable can will not offend at all your lovers of the granulated article—or steal Mr. Doolittle's thunder and send it to 'em in a box. Mr. A. is right on the main point, however. Make your plan and your price according to your situation, and don't be bluff out of it by the brother who has a fancy trade, and who wants you to try the impossible task of bringing non-fancy people up to its lines. If you want your honey eaten daily on the poor man's table, you must compete (to some extent) with home-made sugar syrup. If you can see your way clear to do without the poor man's custom, why, that is your privilege. Page 74.

BROOD-COMB 25 YEARS OLD.

Editor Root's account of the 25-year-old comb is reassuring, and also just what we might expect. Presumably the extra thickness at the bottom is more or less mixt with dried food. I strongly suspect that bees in winter supply themselves

with a small amount of nitrogenous food by chewing these dried masses—one reason why old comb winters bees better than new combs—and also the origin of the little heaps of fine stuff we see on the hive-bottoms. *Possibly* in a land where there was no winter the bottoms would continue to thicken. Even with us an occasional colony does plaster in their cells with black-looking wax till the comb in places is nearly a solid mass. Perhaps that may be much more common in Europe than here. Page 84.

ENTRANCE-FANNING AND QUEEN-FINDING.

And so it is not at the side where fanning bees are, but at the other side that we are to expect the queen. I made and propagated a very natural mistake; so now let us get our heads level on the subject. By the way, McNeal's correction would be misunderstood by a beginner. Strictly speaking, bees do not force air into a hive; they fan it out, and other air follows in by the easiest route. May it not be that it is not the bees but the queen that determines this whole little matter? She feels a current of air, doesn't like it, and directly goes elsewhere. Page 76.

HOW MANY BEES DIE IN WINTER.

On page 88 a beginner asks how many bees die in winter; and Dr. Miller sagely answers, "A whole lot." This suggests, for more than the thousandth time, that we greatly need some common agreement as to what we mean by "the winter." Most of our chunks of wisdom are more or less reduced to fog by the indefiniteness of that term, if they happen to contain it. A colony of 16,000 bees might get thru December, January and February with a loss of only 1,000—and yet "every man of them" die before May 10th. In this case one man would say, "Only a small proportion of my bees died in the winter;" and another would say, "The winter killed 'em, all dead as nails;" and both these men would be telling the truth. Can't we fix things, brethren, so a man can tell a lie when he tries? We seem to have *three* winters. The greater one begins when daily flight ceases, say Oct. 10, and ends when they begin to build up in numbers, say May 1st. (One bad winter I noted that May 6th was the lowest point with my bees.) The lesser winter is of course the three months usually designated as "winter months." Then there is an intermediate sort of winter which has its beginning Dec. 1st, and its end anywhere the season and the speaker may happen to put it—usually at the warm spell which brings in the first pollen—sometimes in March, and sometimes in April. Some-body tell us what we would better do about it.

GENERAL ITEMS

Good Report Bee-Hive Incubator.

I started in the bee-business last spring with 11 colonies of bees, and put 20 into winter quarters in the cellar, and they seem to be wintering all right. I sold three colonies during the summer to an old bee-keeper, and got about 650 pounds of honey all in one-pound sections, which I sold in the home market at 15 cents per pound.

My bees are all "well-bred." I bought some queens last summer from some of our noted queen-breeders, and I don't see much difference between them and my old stock.

I am going to try using the bee-hives as incubators the coming season. My father used to tell me not to "count the chickens before they were hatched," so I will not say how many I will have.

We have had nice weather up to yesterday, when we had a big storm. I can not get along with the American Bee Journal.

G. W. KREMER.

Audubon Co., Iowa, Feb. 4.

Queen-Rearing.

Mr. Prigden's article on queen-rearing (page 401, 1900) is very interesting and important to every bee-keeper even if not in the queen-rearing business, but unfortunately I can say with "Apis Mellifica" (page 170, 1900), that I have read it and reread it 50 times, perhaps, hoping it would clear up, but it is still Greek to me. "Apis Mellifica" complains

SEED OATS

45c a Bu. and up.

The cleanest, heaviest, best yielding oats are Michigan Northern Grown. *Hommond's English Wonder*, *Czar of Russia*, *Michigan Wonder* and *Mortgage Lifter*, the four best varieties. only of one passage, but the whole last page is almost a dark cloud to me.

What a splendid gift Mr. Doolittle has in being able to explain his ideas so clearly and logically, and building up in such correct order one thought after the other, in a way that one must understand.

I tried Mr. Henry Alley's method of queen-rearing with good results, while I made a failure of Mr. Doolittle's, but I am convinced that it was my own fault. I should like to know, too, where I was at fault—whether in transferring or in the colony I used to rear the queens. The result always was that after transferring food and larva into made queen-cells, inserting them into an upper story upon a queen-excluder with a good colony and laying queen below, the food and larva would be gone and the queen-cells empty the next day. The excluder covered only a part of the colony below. Could this have caused the trouble?

I do not advocate increase by swarming, but prefer to build up nuclei and keep down the swarming fever.

J. NOELTING.

Argentine Republic, Oct. 10, 1900.

Bees Wintering Well.

The weather is fine, and no snow as yet. Bees appear about normal in the cellar.

SIOUX CO., IOWA, Feb. 21. F. W. HALL.

Poor Seasons—Hive for Extracted Honey.

The honey-business has been rather discouraging the past two seasons in this section, on account of the dry weather. Bees stored very little surplus, and a great many are dying of starvation this winter; but we are looking for better things in the future.

Which is considered the better for extracted honey—the 8-frame or the 10-frame Langstroth hive?

W. S. SHIELD.

Pierce Co., Wash., Jan. 31.

Has a \$100 Queen.

I had one queen last season that helped me to clear \$100, and I can prove my statement. From her colony and the two swarms which issued from it, I secured 325 pounds of fine honey between March 1st and Sept. 1st. I sold the honey for from 30 to 40 cents per pound—Mexican money—so you may plainly see that I had a \$100 queen.

Bees do well here, but the demand for a good article is very small. Extracted honey brings from 10 to 25 cents per pound, and strained honey from 4 to 6 cents—that is, in "Doby dollars."

W. S. ALLAN.

Mexico, Feb. 11.

Report for 1900—Two Queens in One Hive.

My crop of honey for 1900 was practically the same as that of the two preceding years—an average of 40 pounds per colony. I disposed of all of it in the local market at 14 and 15 cents per pound. I also increased the number of colonies one-third.

We all winter our bees out-of-doors here, and never lose any unless they are very weak.

By way of experiment I am wintering two queens in one hive, with a division-board between the small colonies. These are in the cellar.

A. B. CROSS.

Meigs Co., Ohio, Feb. 4.

Feeding Bees in Box-Hives in Winter.

On page 88 some one asks how to feed bees in box-hives in the winter. Like questions are so often asked that I am tempted to give my practice, which seems to conflict with the answers of others.

I have several colonies in straw-hives, that are sort of honey-combs. I have feeders made of baker's tin, 9x12x2 inches, with thin strips running lengthwise to keep the bees out of the feed. I then make a rim two inches wide, the size of the bottom of the hive, and place this on the bottom-board, with the feeder inside of it. I put the hive in the cellar, or an

adjacent warm room, at night, then fill the feeder with very warm syrup, made of 10 pounds of sugar, 5 pounds of water, and 5 pounds of honey. I then put the hive on the rim over the feed, and give them upward ventilation, to let off the steam or moisture generated by the bees. If the colony is large enough to be worth wintering, the feeder will be empty the next morning. The next night repeat this feeding. I would not advise feeding more than twice in this way, as that is all the unsatisfied feed a colony ought to have in the hive at this time of the year. If one desires they can have it, once in the colony is large and tack on wire-cloth, then close the entrance to the hives while feeding.

If I have a colony in a Langstroth hive that needs feeding, I simply put the feeder on top of the frames with two rods across it, to keep the covering up, fill the feeder, and cover all with the cushions.

I fed bees successfully years ago with this plan, and had fed several colonies the same way in my basement this winter, where the temperature was at least 60 degrees above zero, and have not lost a hundred bees.

While this method is perfectly safe and satisfactory in the early winter months, it would not do at all to try it in the spring months when the bees have become filled with excitement and uneasy for a flight.

GEORGE W. BASSETT.

Washington Co., Vt., Feb. 10.

1900 Almost a Failure—Laying-Workers.

The year 1900 was almost a failure for Missouri bee-keepers. The last three seasons have been very poor, but we are looking for better things next season.

I put 10 colonies into winter quarters in 1899, and did not lose any of them. In the spring I increased to 28 by dividing. Bees swarm very little here, so I did not have any natural swarms.

I winter the bees on the summer stands, with chaff cushions over the brood-frames.

When I examined the bees last spring I found one colony with laying-workers. I gave them eggs from another colony, but they would not start queen-cells, so I gave them more eggs, and changed places with another strong colony, and the strange bees started cells properly, and reared a queen. This colony is now one of the best I have.

My bees stored honey enough for winter stores, but very little surplus. I like the American Bee Journal very much.

R. COYLE.

Vernon Co., Mo., Dec. 20, 1900.

Bee-Exhibits at Farmers' Institutes.

I take great interest in reading the American Bee Journal, and took special pains to have my last year's numbers displayed at our county "Farmers' Institute." We secured space for an exhibit of novelties, fixtures, etc., as well as literature, which was of interest to many. We hope to see good results from our efforts to bring before the people the merits of bee-culture. I see no reason why the honey interests of our country should not have as much attention paid to them in our institutes as is paid to horticulture or poultry. To be literature in horticulture we must call bee-culture to our aid.

Many often ask the question, "What's the matter with my bees?" and doubtless those very persons have never taken a bee-paper in their lives, nor even read one.

CYRIL DOUGLAS.

Johnson Co., Neb., Feb. 8.

The Cry of Hard Luck in Cuba.

It seems very strange to me that although everything I read in the bee-papers about Cuba is full of food-bread and all sorts of good things, yet the writers of these articles are buying new hives by the hundreds. It is hard to reconcile the theory with the practice. One of my friends who talks most discouragingly about it has bought 200 new hives this season, another who has recently published a very pessimistic article is putting in 350 more. Personally, I have always advised my

ARE YOU MAKING MONEY?

DOES POULTRY PAY? It does if you go about it right. It does if you get an incubator that really hatches, and a brooder that really broods. Folks who are using the world famous **RELIABLE INCUBATORS AND BROODERS** are making money because they hatch every fertile egg and produce healthy, vigorous chickens that grow. They are built exactly right. They have never been beaten in practical results. **RELIABLE BANTLING** 200 size, the best made. You'll be interested in it, just the thing for small fry. Send for the best treatise on **20TH CENTURY POULTRY BOOK** written, treats every phase of the poultry question from the standard of practical experience. Write **RELIABLE INCUBATOR & BROODER CO., BOX B-2, QUINCY, ILL.** \$1 but sent for 10c postage.

The Business End of the NEW RUMELY SEPARATOR

Like all the "Rumely Goods" this is simply perfection. When coupled to our New Rumely Rear Geared Traction Engine they constitute a threshing outfit that not only makes big money for the thrasher, but saves grain and money for the farmer. They are durable beyond comparison and when you buy them you are done buying for years to come. Take a little time to think about how it would pay you to own such an outfit, then write us for free catalog.

M. RUMELY CO., La Porte, Ind.

friends not to come here, yet I have just received 500 new hives with some "trimmings."

Some time ago it was stated in the Bee Journal that a subscriber had made a successful shipment of 200 colonies from the States, but in a more recent number he hints darkly at "diseased bees"—yet he has 325 more hives on the way here. And so it goes.

The representative of one of the big supply houses spent a vacation here, and sold thousands of hives, tho we are all crying out that we can't make bee-keeping pay at the present prices—24 cents per pound for all kinds, from white to black. The only reason I see for this is that we feel that the profit to the colony is so small that we must have a great many of them in order to make it pay.

I have just returned from a trip over the north coast. We went for 30 miles thru almost virgin forests, looking for good locations, but it would be impossible to get honey out of there for there is no road. The most of the way we carried our wheels down a river-bed, or followed the paths the deer had made along the ridges. For 25 miles we traveled entirely thru sugar-cane fields, which extend from the coast to the mountains—a block of cane 2500 miles.

The scarcity of good locations is another reason for the cry of hard luck in Cuba.

Cuba, Feb. 4. HARRY HOWE.

A Fair Report for 1900.

Last fall I put 60 colonies of bees into the cellar in good condition, and secured 1,500 pounds of comb honey, which I sold in the home market at 15 cents per pound. I got no increase.

The weather was very dry the forepart of the season, so most of the honey was gathered from fall flowers.

I keep the queens' wings clipped, so I do not lose any swarms, and know just how old the queens are. I make from \$100 to \$300 out of my bees every year.

I recommend the American Bee Journal to all who keep bees. GEO. H. ARINGER.
Meeker Co., Minn., Feb. 16.

Bees Will Die of Starvation.

The past season, in this locality, was a total failure, and I had to feed nearly all of mine for winter. I know of no one else in this locality who fed the bees, and the report is that about five colonies out of every six will die of starvation. HARRY BROKAW.
Richland Co., Ohio, Feb. 15.

Cleanliness Among Bee-Keepers.

I notice what Mr. Abbott has to say on page 55, in regard to cleanliness on the part of the honey-producers. I can verify his statement as far as some of the California bee-keepers are concerned.

I think if we would all be more particular in preparing our honey for market we would receive a much better price.

We have just had the best rain in 10 years. C. E. STEVENS.
San Diego Co., Calif., Feb. 7.

Feeding Bees Grapes—Introducing Queens.

I have been asked how to feed grapes to bees, so will here give my method:

I crush the grapes the best I can, then put them in a large pan, tipping one end a little higher than the other, and having the pulp on the highest end, in the lower end I put some grass, or something of that kind, so that the bees will not drown. After they have taken all the juice, they will gradually work the pulp "down hill."

Having a few more queen-cells than I wanted at one apiary, I cut them out, put them in a pasteboard box, making a few holes in it for air, put it over a strong colony, with a queen-excluding board between, and forgot all about it. When I finally thought of it I found that the queens had hatched, and the bees were tearing away the pasteboard. Since then I have many times used pasteboard for introducing queens.

I once put a comb containing seven or eight

"Vegetable" Gardening Free.—No book ever published on gardening has proved to be more popular nor of more practical value than "Vegetable Gardening," written by Prof. S. B. Green, of the University of Minnesota. It is now used as a text-book in the Minnesota School of Agriculture, in the North Dakota, South Dakota, Iowa, Virginia, Massachusetts, and in the Illinois and Washington State Agricultural Colleges. We have received a copy of the special edition of this book, issued for the Ames Poultry Company, which contains 200 pages, more than 120 illustrations, and treats of the cultivation of every variety of vegetable grown in America. While the regular price of the book is \$1.25 and it well worth it, the Ames Poultry Company is offering it free to every purchaser of a Matthews New Universal Seeder in any of its various styles. These Seeders are unsurpassed by any implement used by the gardener and truck-grower, being adapted to all classes of work, both seeding and cultivating. They are used by Prof. Green in his field-tests. We trust our readers will avail themselves of this opportunity to secure free so valuable a book by so capable an authority. Look up the advertisement in another column; and write them today, mentioning the American Bee Journal when writing.

queen-cells in with about a quart of bees, and when looking after them a few days later I discovered that four of the cells were open, but I could find only one queen. I afterward found the other three in worker-cells, apparently eating honey.

In starting the new colony I put the queen and one frame of brood into a hive, then shake the bees from the frames into the hive, and give the brood to weak colonies. Nearly all the bees given to the queen will stay with her. I also give a frame of brood with a queen-cell or a queen to the field-bees that return; in this way I have more bees, and there is no need to cover the brood to keep from chilling.

B. E. GINER.

Placer Co., Calif.

Is it an Error? Another Was.

On page 78, F. J. Gunzel reports 14,000 pounds of honey from 94 colonies, which, as I figure it, would be an average of about 150 pounds per colony. I wonder if it isn't a mistake—something like the one on page 74, first column, where the treacherous type makes Mr. Aikin say, "The cheapest barrel we could buy would cost us \$100." J. D. GERHARD.

Douglas Co., Kans., Feb. 7.

[Of course, that barrel cost should have been \$1.00. Just the omission of the decimal point—that's all.—Editor.]

Bee-Keeping in the Yazoo Valley.

The Yazoo Valley in Mississippi is a very unhealthy part of the country. I was sick there all summer with chills. It is also a very poor honey locality, as it rains too much. My advice to bee-keepers is to stay away from there. The great bee-keeper who was the cause of my moving there has rendered his 250 colonies into wax. About once in six or seven years they have a good honey-flow from the willows along the Mississippi River, and there are only a few places where that is plentiful.

DANIEL WURTH.

Anderson Co., Tenn., Feb. 4.

Do Bees Select their Future Home Before Swarming?

While wrestling with "la grippe" I have had plenty of time to read the Bee Journal, and have noticed the discussion as to whether or not bees select their future home before swarming. I believe that first swarms always do—second swarms never. First swarms not only select their home, but if it is a tree they clean it out before taking possession.

In 1847, while hunting in the woods near Utica, N. Y., I discovered bees going in and out of a hole in a hemlock tree, and supposed I had found a bee-tree. I went with others the next morning to cut down the tree; it was a sultry morning in June, and before reaching the woods a brisk shower came up, and when we arrived there it was quite cloudy. We could not see any bees about the tree, but we decided to cut it down. As soon as it fell we rushed to the hole to stop it up so that the bees would not get out and sting us. (We knew nothing about bee-smokers in those days.) To our surprise we did not see a single bee. We sat down on the log to rest and eat our lunch; the sun came out bright and hot, and while eating and discussing and wondering what had become of the bees, we heard a roaring sound overhead, and on looking up discovered a swarm circling where the tree formerly stood. After awhile they settled on one of the fallen branches, and we put them in a box and took them home with us. A hot and still evening, as now, prepared to save all wild bees which we found. We cut down 12 bee-trees the past season, and left seven which we did not have time to cut.

In 1852, near this place, I found a swarm in a large oak-tree or supposed I had. We went the next day to cut it, and found the bees working in and out. As soon as the tree fell we rushed forward to stop up the hole, as usual, but only a few were coming out, and these soon disappeared. We cut the tree open and found only a few bees; they were cleaning out the place and getting it ready for

occupancy. Many times since then I have noticed during the warning season that hives that were crammed full of bees would suddenly be almost empty, and I would ensure the one who was caring for them for not attending more closely to business; but in a day or two the hives would be full again, and a swarm would issue. I have known second swarms to go from place to place for a week before settling down to stay, and these were bees which I could positively identify as the year 1894 second swarm of Italians belonging to me de camp, and were found 7 miles away, one week after leaving the hive. I knew they were mine, for they were the only Italian bees in the country.

As to bees carrying both honey and pollen, we hunt bees for a living, and I find that those loaded with pollen, and, in fact, all coming over with dust, fill with honey as readily as those without pollen.

D. H. METCALF

Calhoun Co., Mich., Feb. 8.

Bees Needing a Flight—Propolis on Sections.

Bees have been continued to the hives for quite a long time. They had some small flights in the last three or four days, but I think they are needing a general flight pretty badly. The weather is cold again today, and there is considerable snow on the ground.

I would like it if I could find some way to prevent the bees from depositing so much propolis on top of the sections when using section-holders. Who can tell?

EDWIN BEVINS.

Deahter Co., Iowa, Feb. 20.

Bees Wintering Nicely.

I put the bees into the cellar the latter part of November, and did not see them again until the last of January, when I found them to be as cozy and quiet as could be, and the hives were clean and all right. I took the bottoms off, and found the bees clustered below the frames.

FRED C. LE FEVRE.

Adams Co., Neb., Feb. 6.

Mild Winter—Overstocking.

Up to this time the winter has been so mild that most colonies have consumed about all their stores in brood-rearing. This seems to be the case with hybrids and crosses, especially.

The question of overstocking will be settled around this vicinity the coming season, as an ordinance prohibiting the keeping of bees within one-half mile from the city limits, went into effect Jan. 1st. Several bee-keepers have moved near me lately, having about 350 colonies in all.

We have only a light flow from fruit-bloom in the spring, and the prospects for white clover are not very bright. I believe in scattering 10 cents worth of honey-seedling clovers or flowers for every colony. Sweet clover, when started, will spread with amazing rapidity.

J. C. WALKENHEIMER.

Vanderburgh Co., Ind., Feb. 7.

Paper-Bag Feeders.

In reply to Mrs. Sarah J. Griffith (page 621, 1900), as to using paper-bag feeders, I will have to admit that I have never tried the scheme enough to know much about it. My first trial was a failure. I poured 5 or 6 pounds of syrup into a large paper-bag, tied the top and placed it on top of the frames in the evening. During the night the bag burst, but there was very little loss, as the hive was raised in front. I next made of light manilla paper three or four small bags that would hold about two pounds of syrup. I then opened them, filled them, and placed them on the frames. I tried puncturing them on the sides, near the bottom, and when I looked at them the next morning they were empty, and the bees had enlarged the holes, and were running around on the inside of the bags. That's all I know about it. They might be all right for feeding a colony that was light in stores during the summer or fall, if very heavy paper were used, and the holes made with a check-puncher. For spring feeding the nicest

Seed Success. Farmers, planters, gardeners, and florists all over the country have learned to look forward with the confident expectation of finding something unusually good when the annual seed catalog of H. W. Buckbee, of Rockford, Ill., appears. The new catalog for 1901 will not disappoint them, for it excels in variety of seeds offered, and in general make-up even Mr. Buckbee's former catalogs. It is a veritable guide for the planter, because the public has learned in the 25 years in which Buckbee's seeds have been sold, that they can be depended upon, and that the descriptions in the catalog are true. The cover of the book is graced by a handsome picture, the new beautiful Jackmaoni Clematis, a hardy, continuous bloomer of early growth, a single plant sometimes producing as many as 5,000 blossoms. Among the specialties for which Mr. Buckbee is having the largest demands this year are the famous Quaker Oats, the hardest and healthiest oat in existence, free from rust, and a wonderful yielder; his celebrated Great Liberty Field-Corn first introduced last year, a world-beater in almost every section where corn is grown; Buckbee's Great Western White Dent; the famous Rocky Ford Muskumelon; Buckbee's Mastodon Mangel, and other standard varieties which have been thoroughly tested and proved first-class. Thus, list is too long to give here. Send for his 132-page book and list "the key to success." Address, H. W. Buckbee, Rockford, Ill., and please mention the American Bee Journal when writing.

way I know of is to pour the syrup in as explained by Doolittle and others.

Feeding on top of the hive is bad practice in early spring, as it is apt to get the heat out of the hive, and if it is well packed on top, and feeding at the entrance is liable to start robbing. Square boxes could be made of very heavy paper, that would be all right and cheap. I tried to make a few of them, but a man is very bungling about such work.

Bees might be fed in the spring by placing an empty super under the hive, and syrup put into almost any kind of a paper bag, and put on the bottom-board. Unfished sections left from the previous season are also very nice to use in stimulating a colony. WM. KEISAN, Sullivan Co., Pa., Feb. 4.

The Swate Fields av Nu York.

There's many a field in Nu York that don't be E. L. Field's, an' many av thim do be swate honey-fields, an' let the bees swate it thins an' American things, an' do be loikin' the American Ba Journal jist, an' have since enuf to spake gittin' an' swately whin they have anything to say. The best thing Old Doolittle end do (as he's there on the turf) wad be to Doosonthin, an' go at wanst, froe or no froe, an' turn under that Field an' seed it to swate clover, an' let the bees swate it up a bit wid thim' over it, an' blowin' thier swate breath on the face av it, jist. Now here be yan't the Daddy av Wathers we do be glad to have Old Yuor shnd the Ba Journal ivery wake, an' when we are flush we'll pay the piper, and whin hard up we do be glad to have the Ba Journal come an' cheer an' swaten us. Should the toime come whin we can't git swateness enuf from it to pay, we'll pay pawnt's dlo, an' wid a good-by an' God-speed, quit frinds wid all the swate blyths.

Wid good wishes—an' Old Nu Yorker.

Carroll Co., Iowa, Feb. 8. C. E. MORRIS.

Report for 1900—Rendering Beeswax.

The past season was not a very good one in this locality. I secured about 200 pounds of wax from 10 colonies, spring count, and increased only one. They all have plenty of stores for winter, the hives averaging over 50 pounds each when put into the cellar. What honey I had to spare I sold in the home market at 15 and 16 cents per pound.

I will give my experience in rendering wax from old combs. I pounded and rubbed the old wax into fine lumps, until they looked like pine-sawdust, then I weighed the crush-combs, and found that I had 14 pounds; this I divided into two equal parts, put into bags and soaked for 48 hours, the water being changed twice, and some of the dirt was squeezed out. I put one bag into an iron kettle partly full of water, and boiled it for some time, then I took it from the stove and squeezed it. I repeated this operation three different times, until all the wax was extracted. The 7 pounds of comb made 49 ounces of clean wax, or 43½ percent wax.

The 7 pounds put into the solar wax-extractor, and left in the hot sun at a temperature of from 80 to 90 degrees for about 10 days in June, made 15 ounces, or 13½ percent wax. The slumgum was taken out of the extractor and put into a thin cloth bag in the kettle, and treated the same as the other bag. The slumgum gave 28 ounces of wax, or 25 percent. This shows that a great deal of wax is wasted in the slumgum if it is not boiled and squeezed as it should be.

The outlook for the coming season is promising at present, as the snow will protect the white clover from winter-killing.

ARCHER L. WHITE.

Dodge Co., Wis., Feb. 12.

Care of Plants in Spring.

In the springtime when plants are making strong and rapid growth, particular attention must be given to training them. If neglected in this respect they soon get beyond control, and the only way to bring them into subjection then is by sacrificing a good deal of the growth they have made. This there is no need of doing if the training is begun in the right

way, and at the right time. If a branch is inclined to outgrow others, pinch off the end of it, and keep all such branches from growing by pinching until other branches have had a chance to catch up. If a plant is not bushy and compact, make it so by pinching off the end of all its branches. Keep up this treatment until as many branches have started as you think the plant ought to have. If you desire a plant to grow in tree form train it to one stalk until it reaches the height you want, and then pinch off its top and force it to branch. Save the branches at the top to form the head of the tree. If you want a shrubby plant begin the pinching process when it is small, thus forcing it to branch close to the "pot." The old saying, "as the twig is bent the tree inclines," applies pertinently to the training of plants when in their early stages of development. EMIL E. REYNOLDS, in the Ladies' Home Journal.

CONVENTION NOTICE.

Utah The Utah Bee-Keepers' Association will hold its regular spring meeting April 5th, at 10 o'clock a.m., in the City and County Building at Salt Lake City. All are cordially invited, by pinching out a treatise or pamphlet, the object of which will be to give the best and quickest method to discover, cure, and prevent disease among the bees, and the way to contain other matter for the benefit of the industry, including our State law. We will be pleased to receive communications from any of our bee-keepers upon any subject along the lines indicated. Address, Pres. E. S. Lovejoy, Salt Lake City, Utah, or J. B. FAGE, Sec., East Mill Creek, Utah.

Easy to Answer—The popularity of the Low-Down Farmers' Handy Wagon is not difficult to explain when we see how much easier the Handy Wagon is both on the man who uses it and the horse that pulls it. Being easy to load it saves the work of one man in doing almost any kind of hauling. The tires being wide the wheels do not rut the ground, nor mud, and so the load draws just that much easier.

The popularity of the Electric Handy Wagon, Electric steel wheels, and for that matter, all Electric goods, is easily explained by explanation. It is based on their superiority, which is maintained by careful selection of material and careful construction. The hub is made of a superior cast-iron, fully 10 percent stronger than ordinary cast-iron. The spokes are cast in the hub by a special process, and have a head which effectually prevents their ever pulling out, and therefore remain tight all the time as the wheel turns. The outer ends of the spokes are securely fastened in the tire with a counter-sunk head and a substantial shoulder on the inner side of the tire. The heads are countersunk clear thru, so that the spokes will remain solid in the tire until the tire wears out. Both tire and spokes are made of the best wrought steel, and are treated not to break in the coldest weather or on the rockiest road. The wheels, as a whole, are practically indestructible, and will last a long time.

The Electric Wheel Company, at their factory in Quincy, Ill., manufacture steel wheels (which are sold to farmers to fit any running-gears the farmer may have), hand wagons, tanks of all kinds, reel cookers, feed cutters, and other farmers' supplies. We feel confident that every one of our readers will be interested in their catalog. Do not fail to send for it, and mention the American Bee Journal when writing them.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Feb. 19.—Fancy white comb, 16c; No. 1 white comb, 14½c; fancy dark, 12½c; No. 1 amber, 10½c; fancy dark, 10c; No. 1 dark, 8½c; white extracted, 7½c; amber, 6½c; 7½c; dark, 5½c. Beeswax, 25c.

R. A. BURNETT & Co.

KANSAS CITY, Feb. 19.—Fancy white comb, 16½c; amber, 12½c; dark, 10c. Extracted, light, 7½c; amber, 7½c; dark, 6½c. Demand fairly recalcitrant. Beeswax, 22½c.

W. R. CROMWELL PRODUCE CO., Successors to C. C. Clemens & Co.

CINCINNATI, Feb. 9.—The market for comb honey is becoming very bare, altho the prices have not changed. Fancy white comb is still selling for 10c; no demand for darker grades. Extracted is in fair demand; dark, 8½c; better grades from 6½c to 9c; only white clover brings from 8½c to 9c. Beeswax, 25c.

C. H. W. WEBER.

ALBANY, N. Y., Feb. 11.—Honey market is dull and prices nominal; light stock, but the cold weather is bad for it. Comb, in good order, not candied, white, 15½c; mixt, 13½c; dark and buckwheat, 11 to 12c. Extracted, white, 7½c; mixt, 6½c to 7c; dark, 5½c.

H. R. WRIGHT.

BUFFALO, Feb. 8.—Some more active this week, and may clean up better than expected awhile ago. Fancy 1-pound comb, 15½c; No. 1, 14½c; No. 2, 12½c; 1½c; dark, buckwheat, etc., 8½c to 10c. Beeswax, 25½c. BATTERSON & Co.

BOSTON, Feb. 8.—Fancy No. 1 white in cartons, 17c; A No. 1, 16c; No. 1, 15c; 1½c; No. 1, fairly good demand. Absolutely no call for dark honey this year. Extracted, white, 8½c; 8½c; light amber, 7½c; amber, 7c.

BLAKE, SCOTT & LEE.

NEW YORK, Feb. 19.—Comb honey is being well cleaned up on our market. The demand has lessened to quite an extent, however, we presume, of the high prices which have been ruling. Fancy white still brings 15½c to 16c in a small way; No. 1 white, 13½c; amber, 10½c; dark, 8½c; buckwheat, 7½c. Demand for dark and not much doing. California white honey, 7½c to 8c a pound; light amber, 7c; Southern, from 6½c to 7½c per gallon; buckwheat, 5½c to 5c. Beeswax steady at 25c. HILDRETH & SEGELKEN.

DETROIT, Jan. 19.—Fancy white comb, 15½c; No. 1, 13½c; dark and amber, 12½c; extracted, white, 7½c; amber, 6½c; dark, 5½c. Beeswax, 26½c. M. H. HUNT & SON.

SAN FRANCISCO, Feb. 6.—White comb 13½c; 14c; amber, 11½c; dark, 10½c; extracted, white, 7½c; amber, 6½c; dark, 5½c. Beeswax, 26½c.

Considering the light output of honey last spring from California aparies, present offerings are of tolerably liberal volume and are mostly of amber grades. The market is slow at the quotations. It is reported on good authority that the output of honey is being dealt out in considerable quantity, which accounts in a great measure for the very limited business doing in the pure article.

HONEY MARKET.—We may have a customer within a short distance of you who wants your honey or beeswax. We are in close touch with all the markets; therefore write us regarding your crop, stating quantity, quality, and lowest cash price. References—Either Bank here for any business man in this city.

"Bee-Keeper's Guide."

Liberal Discounts to the Trade.

\$2,000 in Cash Premiums.—This is one of the striking propositions presented to the reader of the seed catalog issued by F. B. Mills, of Rose Hill, N. Y., who has been advertising in our columns for some time past. We have just received one of these catalogs, but space will not permit more than a brief reference to it. Doubtless hundreds of our readers already know Mr. Mills thru their dealings with him in the past, but to such as do not enjoy his acquaintance in a business way, we can only say—send at once for one of his catalogs and see for yourself. It embraces everything in the way of standard field, garden and flower seeds, as well as many novelties in each of these lines. The cash-premium proposition relates particularly to a new variety of oats, the Pan-American being introduced by Mr. Mills this season. It appears he is sending free to certain reliable farmers 2-bushel lots of the seed, the only condition being that a certain portion of the crop is returned to him, and all receiving seed under the above conditions are allowed to compete for the cash premiums, which are many and very liberal. In connection with this same offer, is a free pass to the Pan-American Exposition, which will open at Buffalo, N. Y., this year. We feel sure the remarkably generous conditions of this offer will interest a large number of our readers. The catalog is free. Send for it to-day, and in writing please mention the American Bee Journal. Ask Mr. Mills also for his new lettuce proposition by which another pass to the Exposition is to be awarded.

24th Year Dadant's Foundation. 24th Year

We guarantee satisfaction. **

What more can anybody do? BEAUTY, PURITY, FIRMNESS, NO SAQQUING, NO LOSS. PATENT WEED PROCESS SHEETING.

Why does it sell so well? **

Because it has always given better satisfaction than any other. Because in 23 years there have not been any complaints, but thousands of compliments.

LANGSTROTH on the HONEY-BEE—Revised

The classic in Bee-Culture—Price, \$1.25, by mail.

Beeswax wanted at all times.

CHAS. DADANT & SON, Hamilton, Hancock Co., Ill.

Gleanings in Bee-Culture...

Is an illustrated semi-monthly, 32 pages and cover, at \$1.00 a year.

If you keep only a few bees you can't afford to get along without GLEANINGS IN BEE-CULTURE, as it will save many times its cost the first season. Better get along without almost anything else than a good bee-paper. There is no use in our telling how good GLEANINGS is, as it will speak for itself if you will only let us send you a sample copy for your name and address on a postal. If you once see it we know you will want it.

Look at Our Offers:

Offer No. 21.

For 25 cents we will send GLEANINGS 6 months' trial subscription to new subscribers.

Offer No. 22.

For \$1.00 we will send GLEANINGS for one year and an untested Italian queen valued at 75 cents; but at this low price we reserve the right to send queen some time in July when we have a choice supply.

Offer No. 23.

For 50 cents we will send GLEANINGS from the time your subscription is received till Jan. 1, 1902, so that the sooner you send in your order the more numbers you will get.

Offer No. 35.

Gleanings one year and one untested red clover queen, \$2.00. Gleanings one year and a tested red clover queen, \$4.00; a select tested red clover queen and Gleanings one year for \$6.00. We will begin mailing these queens in June. Orders are already being entered and will be filled in rotation. Do not neglect to improve this opportunity and get some choice stock. Send your order early so you may get the queen correspondingly early in the season.

Offer No. 25.

For \$1.00 we will send GLEANINGS one year and a Clark smoker, postage 20 cents extra. Or, for \$1.25 we will send the Cornell smoker, postage 25 cents extra.

Offer No. 26.

For \$1.75 we will send GLEANINGS one year and our cyclopedia on bees, the A B C of Bee-Culture, of 475 pages.

Old as well as new subscribers may take advantage of these several offers, but all arrears or back subscriptions must FIRST be paid at \$1.00 a year. Refer to these offers by number to avoid mistakes.

AMERICAN BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., MARCH 14, 1901.

FORTY-FIRST YEAR
No. 11.

WEEKLY

MR. O. L. HERSHISER,
*Superintendent of the Apianian Exhibit at the Pan-American
Exposition.*

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & CO.

144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

IMPORTANT NOTICES:

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50c a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Decol" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

Reformed Spelling—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

National Bee-Keepers' Association

OBJECTS:

To promote and protect the interests of its members.

To prevent the adulteration of honey.

To prosecute dishonest honey commission-men.

EXECUTIVE COMMITTEE.

ERNEST R. ROOT, President.

R. C. ATKIN, Vice-President.

DR. A. B. MASON, Secretary, Toledo, Ohio.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

The Bee-Keeper's Guide;

Or, Manual of the Apiary.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW-SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW subscribers to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

Long-Tongued Bees

ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2; or, one Tested Queen free as a premium for sending us FOUR new subscribers (with \$4.00.)

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation—"first come, first served"—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipt, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

28 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 28 cents a pound—CASH—for best yellow, upon its receipt, or 30 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO.

Best White Alfalfa or Basswood Extracted Honey

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are box.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

ESTABLISHED IN 1861 AMERICAN THE OLDEST BEE-PAPER IN AMERICA BEE JOURNAL

41st YEAR.

CHICAGO, ILL., MARCH 14, 1901.

No. 11.

* Editorial Comments. *

The Home Circle.—We begin this week a new department of the American Bee Journal, called **THE HOME CIRCLE**. As will be noticed, it is in charge of Prof. A. J. Cook—a man of excellent ability, wide experience, and a most helpful writer. We trust that thru this feature of the old Bee Journal every member of the family may be greatly benefited.

It would be a nice practice to gather all the family around the fireside, and have some member read aloud the whole of this new department each week. As each paragraph is read it could be discussed or commented upon very helpfully by father or mother, or the older members of the family, and thus pass a most entertaining hour or evening.

We hope, also, that many will avail themselves of the invitation which Prof. Cook extends to all who can do so, to aid by sending to him such items of general interest and helpfulness as may be thought to be suitable. Of course, all such may not be deemed available, but doubtless a goodly proportion would be approved.

It is not our intention to allow "The Home Circle" to trespass upon the space usually devoted to bee-keeping, but we shall likely run fewer of our own advertisements, and devote the space thus occupied to matter that shall be of real value to every member of the family, whether interested in bees or not. We feel that in so doing we will be advancing the good of all, and thus be extending the influence of the "Old Reliable" in a way that will be commended by every one who desires to see it fulfill its highest mission.

We bespeak for both Prof. Cook and "The Home Circle" a cordial reception by every family into which the old American Bee Journal has already won its way.

Home-Apiary of Mr. E. J. Baxter.—On page 151 will be found a picture of the home-*apiary* of Mr. E. J. Baxter, of Hancock Co., Ill. Mr. Baxter is a native of Newark, N. J., but he has lived nearly all his life in Hancock Co., Ill. He is a son-in-law of Mr. Chas. Dadant, and for the past 23 or 24 years has kept bees on a large scale, having from two to four *apiaries* most of the time. He uses large hives, and extracts the greater part of his honey. In reply to enquiries as to his success in the production of honey, he says:

"The book containing my honey-crop statistics previous to 1896 is mislaid, but I can give you my exact returns for honey sold since that time, and some approximation of previous crops. The past five years have yielded me as follows: 1896, \$523.40; 1897, \$1,192.92; 1898, \$407.70; 1899, \$534.98; 1900, \$42.30. The average number of colonies I have kept during this time has been 225. The past five years have been about the poorest, the last being the very worst of all.

"My best years were 1882, 1883, and 1889. In 1882 the bees averaged me over \$10 per colony net, but I don't remember the exact amount.

"In 1883 an *apiary* that I established at Powellton, of 41 colonies, yielded a little better than 23 barrels of honey, one colony yielding 640 pounds. I believe that the total for that year was in the neighborhood of 23,000 pounds from 123 colonies, spring crop.

"In 1889 I harvested something over 23,000 pounds for my own share, besides the one-fifth that I gave to the persons on whose grounds the out-*apiaries* were located. All but five barrels was clover honey, and netted me about \$2,500.

"Our crop is clover, *hearts-ease*, and Spanish-needsle.

"As to the strain of bees, I have blacks, Cyprians and Italians. The Italians have always done the best, in poor seasons usually having plenty of stores to winter on if no surplus, while the blacks are on the verge of starvation.

"I have used Langstroth, Simplicity and Dadant-Quincy hives, and

the latter having given me the best results I have now no other kind. Until the past year I have done nearly all the work in the several *apiaries* except during extracting time, when I have the usual crew of four besides myself, if the crop is good. I now have two out-*apiaries* besides the home-*apiary* shown in the picture."

Mr. Baxter is also a large fruit-grower. He is one of the firm of Baxter Bros., who own several large vineyards and extensive strawberry-beds. Their shipments of strawberries, raspberries, grapes, etc., amount each year to over a hundred car-loads; but E. J. Baxter says that his bees have brought him more profit, for the time involved in their care and the capital engaged, than any other enterprise in which he has ever been.

Making an Observatory Hive.—One of our subscribers in the State of Washington asks us to give plans or directions for building an observatory hive. Also the best location to place it for observation; and he wishes to know whether such can be purchased from bee-supply manufacturers.

Of course, anything in the bee-line can be gotten from the bee-supply manufacturers, if they are told just what is wanted.

Almost any one who is handy with ordinary carpenter's tools can make an observatory hive, something after the style of an ordinary hive, only with glass sides. Perhaps the most successful would be made for only two brood-frames, tho they are often made for one frame. Then the frame or frames can be lifted from the hive with the bees, queen, etc., and put into the observatory hive.

If we were going to keep bees in an observatory hive we think we would have it at the window of one of the living-rooms of our house, having it so placed that the bees could work in and out just the same as if they were outdoors, but have it so arranged that they could not get outside of their hive into the living-room.

Apiculture at the Pan-American.—As we have announced before, Mr. O. L. Hershiser is the live superintendent of the apiarian exhibits at the Pan-American Exposition, which opens in Buffalo, May 1, 1901, to continue six months thereafter. Here is what he has to say in *cleanings* in Bee-Culture regarding the proposed exhibit in the interest and representative of bee-keeping:

Judging from present indications the apiarian exhibit will not be least among the many novel and instructive attractions. It promises to eclipse everything in this line ever attempted, and this, notwithstanding the general shortage in honey-production in many localities within the United States and Canada during the past two years.

This exhibit will be a veritable wonderland, not only for apiarists, but for that larger class of users and consumers of honey. It is designed to make this exhibit educational, as well as entertaining, to the end that the fallacies affecting the pursuit of apiculture may be, as far as possible, rectified.

A model *apiary* will be in operation to show, in a practical way, just how both comb and extracted honey are produced. Exhibits, showing the relation of bees to horticulture, will be a prominent feature, and the mistake of spraying fruit-trees when in bloom will be demonstrated, as well as the absolute necessity of the presence of bees during the season of bloom in order to make horticulture, in any sense, a paying pursuit.

Large quantities of both comb and extracted honey, prepared in the most attractive and appropriate forms for market, will be shown. It is safe to say that this most interesting feature of the exhibit will include the nectarous products of all valuable honey-plants to be found within the Americas and the island possessions of the United States.

There will be a complete and exhaustive display of manufactures therefrom.

Aud quantitative exhibit of honey-plants, as a part of the general outdoor-growing horticultural and floral exhibits, is contemplated.

There will be several large and attractive exhibits of apiarian supplies, comprising specimens of all approved hives and every tool, device, and preparation needed in the pursuit of apiculture.

Several State and Provincial exhibits are already assured, and others are under advisement. It may also be stated that individuals, no matter where situated within the Americas, have an opportunity to

exhibit their apian manufactures and products. One person in this class proposes to install an exhibit comprising a car-load of 30,000 pounds of comb honey, and it is expected that there will be others of great magnitude, especially from localities noted for large productions of honey of a standard and uniform grade, as is the case with the alfalfa of Colorado, the sage of California, and the basswood of Wisconsin. Many of these, as well as some State exhibits, will be of the present season's honey harvest, and will not be installed before the middle of July to the middle of August; but application for space should be made early, in order that it may be provided.

Apiculture is accorded a prominent place in the Exposition, and a special building, in an excellent location, will be provided for the apicultural exhibits, the extent and size of which will be commensurate with the needs and desires of the bee-keepers who will exhibit.

It begins to appear that Mr. Hershiser is going to try to outdo the combined apian exhibits at the World's Fair in 1893, and the Omaha Exposition in 1898. We hope he will succeed. He is a hard worker, and deserves every encouragement in his huge undertaking. Surely, his objects, as stated above, are highly creditable, and, if carried out, ought to help to elevate bee-keeping and the products of the apiary to a higher plane than they have occupied before in the estimation of the public.

The American Bee Journal is ready to do all in its power to aid in making the apian feature of the Pan-American the most entertaining and educative of any to be shown.

"Watch the Bees"—Robbers.—A subscriber at Ackley Station, Pa., wrote us as follows Feb. 18th:

I enclose a clipping from the Farm and Home. It is a good thing we don't depend on farm papers for our bee-information.

The clipping referred to reads as follows:

WATCH THE BEES.—Be sure they have food enough. This can be easily ascertained by lifting the stands. They should weigh at least 75 pounds. If they are not supplied dissolve white sugar in water, enough to make a thick syrup, place in shallow pans and put immediately in front of stand on warm, sunny days. Watch for robbers if this is done. Your own swarms will not rob one another.—M. HALE, Cues Co., N. H.

When it comes true that "Your own swarms will not rob one another," it will no doubt also be true that two roosters will not fight if they belong to the same owner, and there will be no possible chance that one dog will snatch a bone from another unless they belong to different owners. There is, however, a serious side to this matter. In some cases a man will be punished who pretends to practice medicine without proper qualification. He must know enough about the laws of health to be able to instruct his patients as to their health, or he is guilty of crime. Altho less in degree, is it not of the same kind when a journal ostensibly gives instruction upon agriculture, and knows nothing about the matters it treats of? If a physician is subject to punishment when guilty of mal-practice, should not an agricultural paper be punished when guilty of mal-practice in its instruction? Farm journals should give reliable instruction as to bees, or let bees alone.

It says in the clipping that the "stands" should be lifted, and should weigh 75 pounds! If a "stand" weighs 75 pounds, how much should the hive, with bees and combs, weigh?

✱ The Weekly Budget. ✱

MR. JOHN B. YORK, the Father of the editor of the American Bee Journal, died of pneumonia at Randolph, Portage Co., Ohio, Sunday, March 3d, and was buried there March 6th. We returned this forenoon (March 8th) from our old home, where we laid to rest one of the best men that ever lived. He was a sincere, earnest Christian worker, and a member of the Methodist Episcopal church for 55 years, most of the time in some official capacity.

Father was born Aug. 24, 1829, in Starke Co., Ohio, only a few miles from where he died. He left mother and seven children to mourn his departure, four sons and three daughters, the youngest being a son 28 years of age, and the only one unmarried. Father lived to see his children grown up, and all in comfortable circumstances. He believed that to give them a fair education, and ability to look out for themselves, was far better than to leave them financial wealth. He was wise in this doing. We believe father was fully ready not only to die, but also to live again in the Eternal Home, where all his family hope to meet him by and by, to part no more.

MR. A. L. BOYDEN, of the A. I. Root Co., has recently been in Cuba, and gives a report of his trip in *Gleanings in Bee-Culture*. It seems he visited some box-hive apiaries owned and managed by natives. At one of these he desired to take some photographs, but the Cuban bee-keeper didn't quite understand the kodak act. Mr. Boyden continues:

When I went to the lower end of the yard to snap my kodak he came rushing up, gesticulating wildly and talking vociferously. The bees were getting roused up at this point; and as I did not understand his Spanish, I concluded that he was afraid I would get stung. Being a bee-keeper myself, I determined to take my chances, and so held my ground until I had made two exposures (both failures, however), and then went back to the upper end of the yard, where the rest of the company were. When I got there I found I had offended this man very much indeed, for he thought I had come with some sort of music-box to entice his bees away. It is reported that he lost a large number a year or two ago in the same way, and he is very suspicious of anything he does not understand now. We tried to explain the matter to him, but did not succeed in pacifying him.

EDITOR E. R. ROOT has the following paragraph in *Gleanings in Bee-Culture*, with this heading, "York's Patent Double-Acting Bees:"

While we were on the cars en route to the Wisconsin convention, Mr. York poked fun at Mr. Hutchinson and myself on this matter of measuring bees' tongues. Mr. Rankin, you are aware, measures the whole tongue, while we measure from the mandibles to the end of the tongue. When Mr. Hutchinson and I were discussing which was the right way, Mr. York facetiously remarked that he had a plan that was better than either; and that was, to measure from the end of the bee's tongue to the end of the sting. There could be no confusion if we measured thus. And he proposed, further, that Hutchinson and I go into the business of breeding bees that could suck up nectar from "both ends," at one time, something like a patent double-acting double-plunger pump.

When those two editors have queens for sale of the double-acting kind of bees, we will give them a free advertisement. Only we hope they won't develop long stings at both ends, also!

MR. H. T. GIFFORD, of Brevard Co., Fla., we learn from Mrs. F. C. Prange, was shot Feb. 16th by C. D. Reed, a renter. There had been some dissatisfaction about the crops, it seems, but no heated words for over three weeks. Reed used a shot-gun loaded with No. 4 shot, fired without warning, at a distance of 50 feet. Mr. Gifford was unarmed, and was pumping water for his horse. He saw Reed when he aimed, and threw his head and body behind the pump and platform. This saved his life, but he was badly wounded. Mr. Gifford is one of our subscribers, being 62 years old, and most highly respected by the residents of Indian River district in Florida, as well as in his native State, Vermont. We regret very much to learn of this very unfortunate occurrence, and trust that Mr. Gifford will fully recover.

NOT A BEE-HIVE.—The following is told at the expense of an American gentleman who was recently stopping with his wife at Hotel Cecil. On their first evening there he happened to retire somewhat later than his spouse. Arriving at the door of what he imagined to be his room, and finding it locked, he tapped and called, "Honey!" No answer came, and he called again more loudly, "Honey!" Still he got no reply, and becoming somewhat uneasy he shouted the endearing term with his full lung power. This time a reply came, and in a male voice: "Go away, you blithering idiot! This is a bath-room, not a blooming bee-hive!"—London Express.

YELLOWZONES is the name of a valuable tablet remedy gotten up by Dr. W. B. House, of Detroit, Mich. They are intended for the alleviation of all fevers, headaches, coughs, colds, grip, rheumatism, neuralgia, colic, dyspepsia, heart diseases, etc. We have tried this remedy for some of the troubles mentioned, and find it all right. We would advise our readers to send to Dr. House for circular and further information, if interested. Please mention seeing this notice in the Bee Journal, should you write to him.

MR. R. B. LEAHY, of the Leahy Mfg. Co., called on us Friday, March 1st, when on his way to visit Wisconsin bee-supply dealers. We didn't think he seemed as well as some years ago, tho he said he felt better than for some time past. He is taking things easier than formerly, saying he doubted if he would ever again work as hard as he did for others. Nice thing to be able to "let up," we presume, and let others worry over business, etc.

Convention Proceedings.

Report of the Proceedings of the 31st Annual Convention of the National Bee-Keepers' Association, held at Chicago, Ill., Aug. 28, 29 and 30, 1900.

BY DR. A. B. MASON, SEC.

(Continued from page 133.)

THE SECRETARY'S REPORT.

During the past year no complaints have been made to me by any of our members of any trouble in obtaining payment for consignments of honey, but the case to which reference was made at the Philadelphia convention last year has not yet been adjusted.

In 1899, Mr. W. C. Gathright, one of our members in New Mexico, made a small shipment of comb honey to Mr. H. P. Robie, of Sioux Falls, S. Dak., and failed to get his pay. I wrote Mr. Robie twice regarding the matter before I got a reply. He promised to pay, but wanted a little time. After waiting a long time I wrote to him twice, but as yet have no reply, and thinking it advisable to collect the amount if possible, I obtained his commercial rating, which in part is, "He is running a small newspaper called the Successful Farmer. Is of small financial means, and not known to have anything in excess of exemptions, and can not be recommended for general credit dealings."

I informed Mr. Robie of the objects of our Association, and told him that unless settlement was made bee-keepers would be informed as to his method of doing business, and cautioned regarding their dealings with him.

This is the only case in which, during the past five years, I have failed to make a settlement in the name of the Association.

A. B. MASON, SEC.

Pres. Root—Are there any other matters to come up before we adjourn?

Mr. Abbott—The Legislative Committee.

Pres. Root—I will name on that committee Messrs. R. L. Taylor, O. L. Hershiser and Herman F. Moore.

Mr. Abbott—Let me say briefly that the purpose of that committee is to look up the laws in the various States relating to bee-keeping, and to draft such laws as are thought proper in the interests of bee-keepers. Those laws will then be submitted to the General Manager, and when you want a law past in your legislature you send to the General Manager to get a copy of that law, then each State will have a uniform law, and you will have one drafted ready to push thru. I have a man now in Missouri who says he will put one thru our legislature this winter.

Pres. Root—Is there anything further that should come before this convention before we finally adjourn?

Dr. Mason—Nothing is yet known as to the time or place of our next meeting; we have been following the Grand Army Encampment; they have not decided where they will meet; as soon as we have decided you will learn of it in the bee-papers.

Mr. Root—If there is nothing more, I think we may consider ourselves adjourned, *sine die*.

Owing to some misunderstanding no report has been sent to me of the Wednesday evening session by the stenographer, and altho I have twice written about it, and it was promised, it has not been received, and as Mr. J. M. Rankin's paper on "Breeding for Longer-Tongued Bees" was read at that session, I have been waiting the arrival of the stenographer's report before inserting his paper in the report, but as it seems probable no report will be made, Mr. Rankin's paper will be inserted here.

BREEDING FOR LONGER-TONGUED BEES.

The subject which was assigned to me to discuss is one which has but recently been considered by the public as an important one. There are a few men who have been working along this particular line for years, but for some reason or other they have neglected to inform the public as to their results. It may be that they were afraid of being laughed at for working on such a crazy hobby, or it may be any one of a dozen other reasons; but the facts of the case are, that no

attention has been given it by the bee-keepers until the last three months.

When beginning work of this kind it is always well to stop and consider the probable advantages that would be gained if we were successful in accomplishing it. And also count the cost of bringing about the desired change. Then, by mathematical calculation, as it were, we can determine whether or not it is worthy of our consideration. The one great advantage in having bees with a tongue 8 or 9 mm. long, would be that they would be able to gather nectar from the flowers whose corolla-tubes are now too deep for them to work on. There would be myriads of plants whose honey deposits would be of easy access to our bees, which at present are entirely useless except to the bumble-bee. The principal one of these would be red clover. It is a known fact that as the country becomes cleared away, and the wild vegetation with the forests give way to the farmer's corn, potatoes, and hay, that the bee-keeper realizes that it is time to move to better pastures. His crop has become too uncertain to be profitable.

If the honey-bee could reach the nectar in the clover-heads, the bee-keeper would not find it necessary to move. When there is only an ordinary amount of honey in the corolla-tubes, it is of no value to the honey-bee, because it is out of her reach. She is compelled to wait until a moist or favorable time, when the nectar rises to within 3 or 4 mm. of the top of the tubes. What a difference it would make in the honey-crop, in these old sections of the country, where clover comprises half of the hay crop, if a bee could work freely on it!

When beginning this work I sought the advice of several scientific men. I received no help, and no encouragement. One of the most prominent entomologists in the country said that if I had nothing else to do for the next hundred years, it would be a pleasant way to spend my time in trying to accomplish something which was an impossibility. Had I been wise I should probably have taken his advice, but I did not. I went to work to contrive some way of measuring the tongues of the bees. After much experimenting I settled on a compound microscope with an mc. scale, and a camera lucida attachment. The bee was killed by chloroform, the tongue removed, placed on a slide, and held in position by a cover-glass. The image of the scale, as well as that of the tongue, was then thrown on the desk beside the instrument. This, however, proved to be a very unsatisfactory method, as it is a difficult matter, and requires the best of the day to make the adjustments of the microscope.

The method finally adopted was to place the tongue on a slide which contained the mc. scale, then to hold the tongue in place by a cover-glass, and place the whole on the stage of a simple or single lens microscope. By this method it is impossible to get the measurements down finer than .1 mm.; but this is close enough for all practical purposes. Many devices have been made to measure the tongue while the bee is still alive. So far as I have found none of these have been practical. The only fact that is of value that I have obtained from them is that during life the tongue can be stretched to a certain extent, at the pleasure of the bee. Just how much it can be stretched I am not now prepared to say. When I had found a way of measuring I was glad to know that the tongues of a certain colony were comparatively uniform, that is, that each strain had a particular length of its own.

After securing the best stock it was possible to find, queens were procured from this stock, and the selections began. The idea that presented itself to me was to cross and recross two good strains, thinking that we would in time produce something much superior to the original strain. It is by this method that all the improvements have been made in live stock.

It was right here that the difficulty presented itself, namely: How should I control the mating of the queens? Every method imaginable was tried, with little success. I have clipped the tips of the queens' wings, with the intention of impairing their flight; have taken off all the way from a hair-breadth to half the wing, but out of 65 queens thus treated only one was mated.

I then tried the plan of cellaring the nucleus containing the virgin queen, and also a full colony of bees containing drones. Then I released them towards evening, after the drones in the yard had ceased to fly. The results were little better than those of the first method.

The only plan which has given me satisfaction is to keep a colony with drones queenless until toward the close of the season, and after the other drones in the yard are killed off. The virgin queens would generally be success-

fully mated. This plan, however, prevents more than one cross in a season. It has been proven that in the case of live stock, where breeding from nature toward a certain type, that the selections must be from both the male and the female, and of the two the male is the more important. It is necessary, therefore, to control both sides if we wish to develop a longer tongue, because it is not a natural tendency.

After three years of failure and success from these and other methods, from stock which measured 5, 8, and 6 mm., I have made two direct crosses, and the result is stock which measured 6.4 mm.

There is as yet a question as to what will be the outcome of this idea. The problem which confronts us at present is that of mating the queen. When we succeed in this we may experience the difficulty of having our stock suffer from in-and-in breeding, but this can doubtless be overcome.

If some one will take the contract of mating the queens as I want them mated, I would agree to develop the strain of bees with a tongue as long as desirable.

There are three methods, it seems to me, of accomplishing the desired results. One would be to sow a large barren tract on some island in the sea with our June clover. The corolla-tubes of this would be short because the soil would be too poor to grow the clover thrifty. An apiary located in this clover would reap a fine harvest from it because of its short corolla. Then we would gradually lengthen the corolla-tubes by adding fertilizers to the soil, and in a few hundred years we would have bees that would successfully obtain a harvest from June clover. We all know that it is the tendency of animal life to adapt itself to its surroundings. So the bees would have gradually stretch their tongues to reach the nectar in the clover. This method can hardly be considered practical.

The next best thing will be to increase the length of the tongue by direct crossing. This method will, at the best, require many years of careful work. Why not add to this another method which will work in with this one perfectly, namely, to breed a race of clover with a shorter corolla-tube? Plants are more variable than animals, and therefore more easily changed from their original types. There are examples of this all around us. From a small yellow variety of corn, with an ear less than 6 inches long, and a stalk not 3 feet high, we have the large varieties of Dent which stand 10 feet, or even more, in height, and bear two or three ears. Cabbage and lettuce have been selected with a view to the value of their leaves. Phlox drummii has within the last 50 years been changed from a small pinkish flower to the beautiful double white flowers of the present time. All these have been selected with a view to a certain type. Clovers have been developed with a view to a forage crop, and nowhere is there any record of work being done on the flowers themselves. Dr. Beal—one of our best authorities on botany, and especially grasses—said while talking with me on this subject: "A field of clover represents as many and as varied types of the same species as would a field of corn planted from a mixture of all the known varieties." It seems to me, then, that there is a chance to do some good work on the clover. There would be little danger of its going back to its original type, for only the short corolla-tubes would be fertilized by the honey-bees, and the first crop of this clover would yield the seed.

Let me impress upon you that in all probability there are few present here to-night who will live to see bees work freely on June clover. Do not misunderstand me. I honestly believe that it is possible to breed a strain of honey-bees with tongues long enough to work clear to the bottom of a June clover-blossom, but the process will be a slow one, and probably not practical for the ordinary bee-keeper to undertake. What I do think will be practical, and should be done by every bee-keeper, is to keep the longest-tongued stock that it is possible for him to find.

I dare say that next season there will be cataloged by the leading supply-dealers a piece of celluloid with a mc. scale, lense, and a half-dozen cover-glasses thrown in. They will offer the whole outfit for about \$2.00, and every up-to-date bee-keeper will know the length of the tongues of every strain of bees in his yard, and will rear his queens accordingly.

I think that in the past the ordinary bee-keeper has been too likely to rear his queens "just as it happened," or possibly has paid special attention to the three or five yellow bands. This is all wrong. When selecting a work-horse we do not pick out a sharp-backed, slab-sided horse just because he works willingly. We find a square-built, blocky

horse that has the ability as well as the willingness to work. Why not apply the same horse-sense when selecting our breeding stock in the apiary?

If this method of selection is followed for a few years there will be no more short-tongued bees in your apiary. Then, too, you will not see one colony working on some vile weed, and storing strong, black honey while the colony beside it is storing beautiful white honey from second-crop clover, or from some other plant with a deep corolla.

J. M. RANKIN.

REPORT OF THE COMMITTEE ON A MODEL SCORE-CARD.

The committee appointed at the National convention in Chicago, to draft a model score-card to be used in judging bees, honey, etc., at fairs, was appointed so late in the meeting that they could not get time to decide on various points, and after much corresponding they have decided to offer the enclosed score-card—not as a perfect score-card, but as a help, and with the hope that it may be tried in various parts of the United States, and then be so modified by another committee at the next meeting as to fill all demands:

General Display	Comb Honey	Quality 25	Variety 5 Perfection of capping .. 5 Completeness of .. 5 Straightness of comb .. 5 Sections, clean and neat 5
		Quantity 25 Attractiveness 50	Each variety of honey to be distinct of its kind.
	Extracted Honey	Quality 25	Variety 5 Body 5 Flavor 5 Style of package .. 5 Kinds of packages. 5
		Quantity 25 Attractiveness 50	
Single Case Entry	Comb Honey	Not less than 12 pounds nor more than 25 pounds. Points of judging as above, graded as white, amber or dark.	
	Extracted Honey	Points of judging as above, graded as white, amber or dark.	
		Granulated. (Separate entry.)	Variety 5 Fineness of grain. 5 Color 5 Flavor 5 Package 5
Nucleus of Bees in Observatory Hive	Color and markings..... 30		
	Size of bees..... 20		
	Queen 20		
	Brood 5		
	Quietness of bees 10		
	Style of comb..... 5		
Queen-Bee	Style of hive..... 10		
	Each race of bees to have the markings and color peculiar to its race.		
	Quality 50	As per nucleus of bees.	
	Variety 25		
Style of cage .. 25			
Beeswax	Color 30	Not less than 10 pounds.	
	Purity 30		
	Grain 20		
	Display 20		
Implements and Supplies.	Number of kinds 50		
	Appearance or attractiveness 50		
Bakings	Greatest number, sweetened with honey, recipe for making with each exhibit—1st Prize.		
Candies and confections			
Honey-Vinegar			
Honey-Wine			
Fruits (canned)			

Respectfully submitted,

N. E. FRANCE,
W. Z. HUTCHINSON,
F. WILCOX,
R. C. ATKIN,
O. L. HERSHISER,

Committee.

In several places in this report Mr. and Mrs. R. C. Aikin's little daughter has been credited with having entertained the convention with songs and music on the piano, but Mr. Aikin writes me that Mr. and Mrs. Aikin's little daughter was our entertainer. It was a very easy matter to make such a mistake when two such bright and winsome Misses of so nearly the same age were constant attendants on our sessions.

A. B. MASON, Sec.

[THE END.]

No. 5. Extracted Honey Production.

Machinery Needed—Freeing of Impurities—About Heating—Why Some is More Watery Than Other.

BY R. C. AIKIN.

IN addition to the extractor there are knives, knife-pan, and oil-stove to heat same, capping box or can, strainer, and one or more tanks. The larger the tank the less trouble and the better the honey. Some use a tank of about a barrel capacity, a real barrel sometimes serving the purpose; such will do for a very few colonies. I will not specify a definite size of tank, but rather tell you what you ought to do, and then you can judge for yourself of the size best suited to your needs.

In extracting it is rarely that any foreign substances get in the honey but bits of wax and propolis. Wax weighs, I think, about 7 pounds to the gallon, being lighter than water, which is in round numbers 8, honey about 12, and propolis between water and honey. I will say, parenthetically, that if you are melting wax that has propolis in it, be careful not to let it get too hot, for the propolis settles to the bottom of the boiler and will burn there and stick fast to the boiler-bottom. I have just been melting a lot of top-bar scrapings composed of propolis and bur-combs, and altho I thought I was not letting it get too hot, yet it burned on the boiler-bottom.

Since the specific gravity of wax is but about $\frac{1}{3}$ that of honey, and propolis slightly heavier, but still lighter than honey, both will float. The thinner the honey the quicker will the impurities float, but it is very hard to have it thin enough either to do a good job of straining thru cloth, or to float out these substances in less than several days. Well-ripened honey should be at least three or four days settling at a temperature of about 100 degrees, and even then there will appear more or less specks after drawn into the shipping package.

Suppose you want to extract one or two thousand pounds in a day, and have but a 500-pound capacity settling-tank to receive it—you can neither strain nor settle it properly in that time unless heated to considerably over 100 degrees—I should say not less than 125°. The most practical way is a tank of a capacity to hold the honey so you can let it settle for at least a week, and even then it ought to be in a quite warm place. If you want to do good work, and put out a well-ripened and a clean and nice liquid, use both time and heat liberally.

For several years I used a tank of 1100 pounds capacity, but when extracting 1,000 or 2,000 a day—even 600 or 800 a day—several days in succession, I found my tank altogether too small. A tank 2 feet across and 4 feet high will hold about 1,000 pounds. I now have one 5 feet across and 6 feet high, which holds 5 tons, is made of galvanized steel, and never overflows with a day's extracting. The outlet is in the bottom; the pipe is elbowed out beyond the tank, and all is set on a circular stone foundation built from the cellar floor to about two feet above the ground floor. A brick casing is built about the tank with two to three inches space between tank and brick, until the top is reached, when the brick is drawn in against the tank and mortared airtight to retain the heat.

In the circular chamber beneath the tank is a range stove, and on this is where I melt honey, wax, and such work, and a little fire there helps to keep the tank warm. The chamber being of stone, and nearly the whole structure of stone, brick or metal, I can leave a roaring fire and no fear of a burn-out.

Speaking of heating honey, it does not absorb heat as freely as water. Set a chamber or hive of combs of honey in a warm room, and it will be many hours in getting warmed thru, at as high a temperature surrounding as 100 to 120 degrees. I often bring in a lot of extracting chambers and store them, and before extracting I keep the room at well nigh 100 degrees for about two days, then extract. I have so treated several tons, warming for extracting after the honey season was over as late as November and December.

The consistency of honey varies quite materially, much depending on conditions while being gathered. If the flow be very slow, capping is delayed and the cells remain open, and the honey is exposed to the evaporating process for so long that it becomes very thick; but with a rapid flow the cells fill rapidly, and the free honey and constantly full honey-sacs cause a free secretion of wax and prompt sealing, sometimes even before the honey is sufficiently ripened. When nectar comes freely it is dropt into any available open cell, among the brood, near the entrance, in fact anywhere where there is found an open cell, big or little. When the flow lets up, or stops, then this scattered honey is gathered from here and there and stored regularly. Even a rainy day serves as a chance to put things to rights in a much disordered house caused by the previous rush to get all that was to be had while it was available. This unevenness will be observed at times by thick and thin streaks in the same combs, and some parts of a comb will extract much more freely than another.

All honey intended for table use should be put thru a settling-tank, and well settled. If it were feasible to get the honey heated to about 130 or 140 degrees before straining, then it would be possible with large but fine and close strainers to properly strain out the impurities; but the easiest way is large settling-tanks. The large tank, and time given, make a much more even grade of honey than can otherwise be obtained except by freely using heat. I am an advocate of applying some heat to the honey, but too much would be worse than none at all.

Another thing essential in a well-equipped honey-room, is handy water and washing arrangements. Where it is possible there ought to be water on tap as in waterworks of cities and towns. The water may be kept in a tank so that it can be drawn at any time. A waste-way or sink should be provided for dirty water, and a barrel with a cloth over it for all honey-washings, such as of cans that have had honey in them, honey-strainers, etc. This sweetened water can be poured into the barrel thru the cloth tied over the top, thus straining it as it goes into the barrel. Such sayings will make first-class vinegar, and help out in the revenues.

Larimer Co., Colo.

Do Bees Injure Fruit by Taking the Nectar From the Flowers?

BY G. M. DOOLITTLE.

A CORRESPONDENT writes that a neighbor of his thinks he ought to give him several pounds of honey for the injury which was done his fruit from his bees taking the sweet out of the fruit-blossoms, this hindering the fruit from perfecting as fully as it would have done, had the bees not so taken the sweet, ending his letter in this way:

"Will you please tell us in the American Bee Journal whether there is anything in this claim? I do not wish to give out any honey as pay for damages, as it would be establishing a bad precedent, altho I generally give my neighbors several pounds of honey each, every year, for I like to see them enjoy it; and it also helps to smooth over any rough feelings which the bees may cause in any way."

I like the spirit of the last words from our correspondent very much, and know from experience that the giving of a few pounds of honey to all near-by neighbors will smooth over all bee-spots on drying clothes, an occasional sting gotten by a bare-footed child stepping on any bruised or partly decayed fruit which may happen to have a bee in or on it, etc., and I believe that nothing pays me better than the giving of some of the "first fruits" of my honey to those who may have a chance at some time or other to be annoyed by my bees. But while I so believe, I would never give out a pound of honey as payment for any damage done to flowers of any kind by bees working on them, for no damage is ever done. In fact, it is always the other way. The bees always help in perfecting any fruit which is visited by them while the fruit is in the blossom or flower

form. It is only from jealousy, coming from that innate weakness common to all, causing a restlessness to come over others by seeing the bee-keeper prosperous, that such demands are made of us bee-keepers, and to show any concession on our part at this point would be to "let down the bars" for a still greater call upon us.

No sooner did it go out by a gossip of our neighborhood, that "Doolittle was making money out of his bees," than a few about me began looking around, and when they saw bees at work on the bloom in their orchards, meadows and buckwheat fields, they began to reason that Doolittle was getting rich from that which *belonged to them*, and from this sprang the thought that the saccharine matter found in the flowers was placed there for the development of the fruit; and as the bees took away this sweet as fast as it was secreted by the flowers, an injury must result to the product coming from these flowers and their fields, which injury did much to enhance Doolittle's gains.

Since being in the queen-business more largely than in the honey-business, I have heard less of this than formerly; but from my own experience I doubt not that every prosperous bee-keeper has either heard something similar to this, or, if he has not heard it, his neighbors have talked it when not heard by him. I have even been asked for ten pounds of nice basswood comb honey as pay for what the bees gathered from a ten-acre field of Canada thistles, which the owner of the land had allowed to grow up thru his shiftlessness, he arguing that a pound of honey from an acre was a very light toll, indeed. When thus approached, I have always assumed the attitude of the injured or grieved one, and demanded a *cash* return for the service rendered the crop by the bees causing greater *fruitage* thru their properly pollinizing the flowers work upon, and have always so presented my arguments that every party so approaching me has gone away convinced that I was right in claiming that better results always attended any crop which was visited by the bees in the blossom form.

I take a little different view of these matters than do most other people, going back to the creation of all things and telling how all fruit or grain of any kind was an entire failure till insects were created to visit the flowers which secreted *nectar*, while those that did not secrete nectar bore fruit as perfect then as to-day. Of course, thus far, all is a matter of conjecture, but it serves the purpose of getting the thoughts of the one talked with from what he considers a grievance, over to a line of thinking where he is at least a little pliable toward the bee side of the matter. From this I go on to explain how that the first object of nectar in the flowers was *not* for the perfecting of fruit, or to be used as a food or luxury for man, nor even to sustain the life of the bees, but as a means to an end, and that this end was that *insects of all kinds* might be drawn to the flowers so secreting, that the fruit, or female blossoms of plants which could not possibly be fertilized in any other way, might be fertilized thru the agency of *insects* which would be attracted to these flowers by the tempting and attractive morsels of sweet they spread out before them as a sumptuous feast, while honey as food for the bee and for the use of man came in as a secondary matter or item.

I then proceed to dwell on insects other than the bee, and show that these out-number the bees by scores, as all close observers well know, showing that to claim damage of any one from these would be something not to be harbored for one moment.

Having gotten the thought now fully on my side of the matter, I next proceed to quote from Gregory's treatise on squashes, where he says, "The primary reason why a squash grows, is to protect and afford nutriment to the seed"—the use of it as food being a secondary matter, and thru this line of reasoning prove that the primary object of the nectar placed in the blossoms of the squash was to draw insects to the blossoms, as the female blossom is of such shape, and being hid down in the leaves, that pollination could not be effected in any other way, and thus neither seed, nutriment, nor anything of the kind could be obtained, were it not for the insects which were attracted by that little nectar which was placed in these for the *sole* and *only* purpose that the seed to the squash might perfect.

I then go on to give Gregory's experiments of covering the female blossoms so no insects could visit them, and without a single exception, every such covered squash-blossom was abortive. I also tell how bees were once banished from the town of Wenham, Mass., the result being that no perfect fruit was found in the interior of that township until the bees were requested back again; winding up by asking, "Why, then, is nectar placed in the flowers?" This nearly always brings an answer more or less favorable to

the bee, which I make more impressive with, "To attract insects that the blossoms may be properly fertilized, *primarily*; and, secondly, for food for these insects, which food for insects, in the case of the bee, is utilized by man." And by this time the man or woman who came with a grievance, as he or she thought, is won over to the *insect* side, if not to the bee side, and I hear no more of paying for damages done to flowers by the bees.

Let our correspondent try this line of reasoning, rather than giving any honey or anything else to pay for damages claimed to be done thru his bees to the flowers in his neighbors' fields or orchards.

Onondaga Co., N. Y.

What About the Hare?—Will It Become a Pest?

BY FRIEDEMANN GREINER.

THE reports on the Belgian hare in this and other papers are somewhat conflicting, and people's opinions go widely apart. Mr. Martin says in *Gleanings in Bee-Culture* that after an absence of nine months from Los Angeles he finds the hare-business—which had been in a flourishing condition before he left—dead and gone; and, further, that the hare-meat can not compete with other meats.

Mr. Morrison in the same number of *Gleanings* says that one firm in Melbourne sent 5,000,000 canned and frozen rabbits to England; further, that he can buy in Bermuda a whole imported canned rabbit for 24 cents.

Mr. Martin's and Mr. Morrison's statements do not exactly harmonize, and yet are not so very far apart. Mr. Morrison does not speak of the hare-business from the fancier's standpoint. Mr. Martin evidently does. The conservative observer has been quite sure from the very beginning that the life of a \$500-hare boom would be short. There may be a few, who in the future will be willing to pay \$5.00 or \$10 for a pedigree hare, but the majority of hare-growers must grow the animal for meat-stock and so can not afford to pay exorbitant prices for breeding-stock, particularly as the difference between the 50-cent hare and the \$500 animal does not lie in the latter's greater size, vigor, higher quality of the meat, or any other important feature, but merely in the slight difference of his color, which disappears when the pelt is pulled off. The 50-cent hare has more white hairs on the legs and underside than the other, but is just exactly as good for the table. That is what we raise the hare for, and therefore can not see good business sense in it, to pay these fabulous prices.

Why the meat of the hare could not be made to compete with other meats I fail to see. It certainly does in our own home, and others that I know of. We like variety. A few years ago we got tired even of capon meat. My better half said she did not like those great 10-pound carcasses; they lasted too long. A hare seldom dresses much over 4 pounds and we can "make away" with one at a meal, perhaps leaving just a few of the choicest slices to put into the dinner-pails of our children to take to school. We aim to have rabbit on the table once a week at least; we enjoy it and I believe when the public becomes acquainted with this diet, there will be a call for it.

Mr. Morrison also says that in Australia the rabbit can not be called a pest. I judge from my experience that it will not become a pest here. I can understand that in a congenial climate, with no enemies, the liberated hare might increase rapidly and in the end overrun the country. But there is no danger of that in America where his foes are legion, and the numbers of hunters outnumber the game. One might turn out a large flock here, but he will not see them increase to any appreciable extent. My experience is they soon decrease in numbers. It would indeed be a lucky accident to see a young outdoor brood of hares grow up to maturity unharmed. A grown hare may for a time hold his own, but he is always in danger, and I would not want to keep a valuable animal except within a tight enclosure.

Not long since the Illinois State Horticultural Society passed a resolution concerning the hare as follows:

"Resolved, That it is the sense of the Illinois State Horticultural Society that hares should in no case be permitted outside of strong cages or enclosures, and that we earnestly request the general assembly of the State of Illinois at its approaching session to enact a law providing, etc., and affixing suitable penalties upon their owner in the event of their being allowed to escape, etc."

Senator Dunlap, president of the society, stated that it

would probably be better if the society would petition the legislature to enact a law to prohibit the growing of the hare within the State. A comparison was even drawn between the hare and the English sparrow.

These good people are unduly scared. I will admit it might be unwise to turn a large lot of hares loose into a young orchard in the winter-time. I very frequently turn out 10 or 12 of the animals at any time with 600 young fruit-trees growing near by, which I would not have injured for all my hares. Yet I have not the slightest fear that any of the trees will be damaged. The fact is, I have never had a tree injured, neither by the wild rabbit, which within three years was very plentiful here, nor by my hares, except when the fruit-trees had been planted in the hare enclosure. The woodchuck is the destroying foe among our fruit-trees—not the hare; and the States could well afford to pay a bounty for every specimen killed; the hunters would take care of the hares. In some localities nurserymen sustain heavy losses by the work of wild rabbits; it is true; but a few hunters with dogs and ferrets will clean out (glad to do it) an infested district in a short time. I do wish we had more wild rabbits.

The hare—because less cunning—could be subdued and cleaned out much more easily and quickly than the wild rabbit. However, nobody need be afraid that any hare-grower would liberate and give up ownership of his stock as long as they are as valuable for food as they are. There is absolutely no need for legislation against the hare altho I believe California has a law against liberating hares.

Sometimes when I wish to dispose of surplus stock, to make room, I kill a number of them at a time, stew the meat and can it in our regular one or two quart glass-cans. Thus prepared it is ready any time for lunches or other culinary uses.

I am not sure that the hare industry is the coming industry, as Mr. E. T. Abbott puts it, or that it ever will assume gigantic proportions as to become a leading industry, but I am sure that it will always be and remain a pleasant auxiliary for the production of choice meat, for one's own table at least, and at a very low figure. In my individual case, if I had several hundred grown animals now on hand I could very easily dispose of them at 15 cents per pound.

Ontario Co., N. Y.

A BROTHER'S TESTIMONY.

I will add that my brother Friedemann, is hardly enthusiastic enough about the value of the Belgian for meat stock. In quality, the meat is unsurpassed—I believe even unequalled—by the meat of any other domestic animal, the capon not excepted. A well-roasted young Belgian hare is a treat, indeed.

In a general way, Friedemann has given the facts in the case.

T. GREINER.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Death-Rate of Bees in Cellar-Wintering—A Foul-Broody Deal.

1. I put 72 colonies of bees into the cellar Nov. 22d to the 26th, just after a good flight, but found many dead bees on the bottom-boards, which were all cleaned out. About one-third had a $\frac{1}{8}$ -inch entrance, and the balance $\frac{1}{4}$ inch, and nearly all of the latter were raised and $\frac{1}{2}$ -inch blocks put under the front end. As there seemed to be more dead bees than usual on the cellar floor, I made a note of all, swept up since Jan. 16th, which is as follows: Jan. 16th, nearly two quarts, and one hive spotted; Jan. 24th, nearly two quarts, and four hives spotted; Feb. 1st, $1\frac{1}{2}$ quarts, and eight hives spotted; Feb. 7th, $1\frac{1}{2}$ quarts, and 12 hives spotted; Feb. 14th, two full quarts, and 15 hives spotted.

Is the above an average death-rate, or is it above the average? Would it be best to put the bees out for a flight on a good day, and then return them to the cellar? The

cellar is rather damp; it was tiled Nov. 1st. The temperature has been from 40 to 48 degrees.

2. A bought bees of B—7 colonies at \$3.00 each, in April, to be paid for with honey produced by the bees, (but not to be confined entirely to 7 colonies). Six of the seven were affected with foul brood, unknown to the buyer (and supposedly unknown to the seller). The bees being black, part of them were used for rearing queens to queen the rest, and divided into nuclei. (Don't say A was foolish—he did not know there was any foul brood in Iowa.) Result: 11 colonies have been treated for foul brood, 2 of them absconded, one full colony and one 3-frame nucleus were sulphured, and three of the treated ones died during winter, probably from the boiled honey; \$7.00 has been paid. Now, without any thought of the legal points in the case, what would be right and just to both parties? Ought A to pay the full amount to B, or has he paid enough? Only one of the seven colonies stored any surplus honey.

IOWA.

ANSWERS.—1. There is nothing very unusual about the mortality, but so many hives being spotted so early in the winter gives occasion for some uneasiness. When a cellar is damp it needs a higher temperature than when dry, and it is possible that a higher temperature would have prevented all spotting of the hives. The temperature was rather low in any case if it ranged evenly from 40 to 48 degrees, for that would be an average of 44; and if most of the time it kept near the lower limit the case was still worse. Unless they are very bad, it is hardly advisable to put them out of the cellar until they can stay out. Experience has shown that when put out and returned to the cellar they are not likely to do very well. But it may be advisable to put them out earlier than you would do if they were perfectly healthy.

2. The probability is that the moral and the legal view of the case would closely coincide. If a merchant were to sell you by mistake sand instead of sugar, he ought not to be paid more than the value of the sand, and the fact that he was ignorant of the character of the material sold would not in the least degree enhance the value of the sand. The cases are not exactly parallel, for while one might be willing to accept sand at a price sufficiently low, he would hardly want to accept foul brood without being paid for taking it.

A Beginner's Questions.

1. I had one colony of bees last spring, and they worked well at first, but after the first swarm they stopt work. What made them do that?

2. Four years ago I had a colony that swarmed three times. They worked all the time till all the flowers were gone. I put all the colonies into the cellar and in the spring they all died. Do you think the cellar was too damp for them?

3. How long does a worker-bee live—40 or 60 days?

4. How many drones does the queen have with her during the working season? NEW YORK.

ANSWERS.—1. The probability is that there was no work to be done, that is, no honey in the flowers. Sometimes the flow ceases when there is no apparent reason for it. Then it may start again without any difference that one can see. It may be, however, that you mean that this one colony stopt work while others continued to work. The fact that it swarmed was enough to account for at least a very great decrease in the amount of work, because work can only be done where there are workers, and when that colony swarmed most of its workers went with the swarm. You will find it invariably the case that when a colony swarms there is a great falling off in the work of the mother colony.

2. It is impossible to say without knowing more about the case. If the cellar was very damp, that would of course be something against their chance of wintering well. But no matter how good the cellar, you ought not to expect all to winter well when a colony swarms three times. Under ordinary circumstances, two or three of the colonies would be weak for good wintering. The mother colony would be greatly weakened by so much swarming, and the second and third swarms would hardly be strong. But that does not account for the death of the first swarm, and one can only guess that a cellar too damp or too cold, or too little ventilation of hive or cellar, or both, or some other thing was the cause of the loss.

3. The life of a worker-bee depends upon the amount of work done, and so to a great extent on the time of year.

A worker that enters its career just after all work in the field is over has little chance to wear itself out with work, so it may live six months or longer. If it starts in when there is work for all hands, say the last of May, it will live about six weeks.

4. There is no rule as to the number of drones to be found in a colony during the working season. Other things being equal, the number is likely to be more with an old than with a young queen. The harvest has something to do with it. If the harvest is fitful or poor, the chances are not so good for a lot of drones to be allowed in the hive. The combs make a difference. Less drones will be found in a hive with little or no drone-comb.

Building Up Weak Colonies—Stimulating Brood-Rearing by Feeding.

1. I read that sometimes even very weak colonies—say covering only one comb—build up in very good seasons so fast that they make not only strong colonies, but even store some surplus honey. Now, do you think it would be advisable to-day to divide a colony covering eight frames into eight nuclei, giving each a young and fertilized Italian queen? As we expect a very good season, if the strong colony would give 300 pounds of surplus extracted honey, would not the eight colonies (or nuclei) build up so well that I could get from 60 to 80 pounds from each?

2. Is it of any use to feed for stimulating brood-rearing in the spring, if the colonies still have plenty of honey? What can I do to stimulate them? CALIFORNIA.

ANSWERS.—1. It is true that a nucleus with bees enough to cover only one comb may build up into a strong colony and give some surplus. It is also true that a strong colony may go thru a good season and yield no surplus whatever, being weaker in the fall than in the spring. Both are very exceptional cases, and it will not do for a beginner, nor indeed for any one to take either extreme as a basis. There is of course a possibility that an experienced bee-keeper might divide a colony covering eight frames into eight nuclei and obtain from each a surplus of 60 to 80 pounds in your wonderful California. The probability is that he would obtain no surplus whatever, if indeed no feeding were necessary. It is hardly advisable to start a nucleus with less than two frames of brood with adhering bees, and even then you should not expect wonders.

2. It is a little hard to say. If there is an abundance of stores in the hive, stimulative feeding may do little or no good, and if unwisely administered it may do harm by starting the bees flying when they would be better off in the hive. A beginner may do as well to see that a colony has abundance of stores, and then let it alone.

Mice Trying to Reach the Bees.

My bees have had no flights for over a month. I find that mice have tunneled thru the snow to get at the dead bees as they fall at the entrance. They have gnawed some trying to get inside. Do they do any harm? If so, how can I avoid it? PENN.

ANSWER.—Of course the mice do no harm by eating the dead bees thrown out at the entrance; but they may do harm, and a whole lot of it, if they make their way into the hive. Mice in a hive will eat the honey and the bees, and they will destroy the combs. If they did neither of these things they should still be outlawed because of the harm they do by disturbing the bees at a time when entire quietness is desirable. Of course the entrance should be large enough so that a very little gnawing would be necessary for a mouse to gain admittance. But there is no need to admit the mice were the entrance ten times as large. Close the hive with wirecloth having about three meshes to the inch. That will allow free passage for the bees but exclude the mice. If not convenient to get such wirecloth, you may make a fence of wire-nails at the entrance, setting the nails about a quarter of an inch apart.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription *a full year in advance*, we will mail you a Wood Binder free—if you will mention it.

* The Home Circle. *

Conducted by Prof. R. J. Cook, Claremont, Calif.

THE HOME CIRCLE.

Isn't that an excellent heading for a new department in the "Old Reliable?" What is there on this mundane sphere comparable to the home? Demolins in his "Anglo-Saxon Superiority," which every one of our readers would do well to read and study, puts Home as one of the chief reasons why the Anglo-Saxon has outstripped all the Latin races.

It is said that the French have no word for home. Aren't they to be pitied? How the very word "home" stirs us all, and how the very thought of it makes us purer and better. If the word and the thought count for so much, what shall we say of the thing itself? Demolins' work has gone thru many editions and has stirred the French people deeply.

Another work which all of us will do well to read very carefully—I have read it twice—once in the Outlook, and again in book form—is, "America's Working People," by Charles Spahr. Over and over again our author shows how much the home has to do in making the good neighbor, the thrifty citizen, no less than the patriot. In speaking of homeless workers, Spahr says, "And thus the greatest incentive to thrift was removed." He adds further, "On the side of citizenship, the gains that come from home ownership instead of tenantry are still greater."

It were quite superfluous to talk to any Americans regarding the priceless boon that we as a people possess in our delightful homes. What gives one a heavier headache than to see a man or woman plodding along thru life alone or homeless? Our bee-keepers are almost universally blest with beautiful homes. I have so often enjoyed the fellowship of these little "heavens on earth" that I speak with no light emotion regarding them. How well I remember spending one Sunday in one of these, a little west of Chicago. The man's name was not Dr. Moth, but he did have a charming home. What a lovely Sunday that was. What solid delight we took, all thru its hours and away into the night. It was a home where the best love and fellowship reigned continuously. Ah, better than this, it was a home where God's word was read, studied and revered. It was a home where Christ's incomparable teachings were obeyed and where His spirit shone forth. I have been a better man, I am sure, ever since I made that Sunday visit. How we did enjoy the morning talk, how precious was the hour of family prayer, how delightful the church service, and how long-to-be-remembered the Sunday-school where our host was (and we attend; and what a blessed afternoon and evening completed this, one of the most delightful days of my life. How often I have wished that I might do something to multiply such homes. It is the privilege of every one of us to help to make at least one such center of good purpose and wholesome influence.

Perhaps I have said enough at present in regard to the Home part of our department. Especially is this true as we shall weave in every week hints and thoughts of how the glory of the home may be promoted, and its blessedness made to touch with its hallowed influence many who perhaps have never enjoyed one of their own "Home Circle." I like that word "Circle." A circle has no end; neither has the influence of a good home. Who of us does not remember the cozy circle of our childhood? How delightful it was as we gathered about the table—father, mother, brothers and sisters—in the long winter evenings. One read the fascinating book while others at the apple-paring or in restful leisure listened and commented. Ah, those were precious circles! Father, mother, possibly some of the others of that gracious home circle mayhap have now gone to the greater circle which indeed shall have no end. But the influence is not gone. The mother-love still is the leaven that sweetens and brightens our hearts and lives; the father's good counsel and worthy example still guide us away from life's pitfalls; the loving brothers and sisters still walk by our side tho long gone to the realms of the blest. Many of us have since formed the home circle for ourselves, only to repeat what glorified our childhood homes.

It is indeed a good department of the old American Bee

Mr. E. J. Baxter and his Home Apiary, of Hancock Co., Ill.—See page 163.

Journal. It will be my earnest hope and determined effort to bring into it something each week that may happily quicken joy and lessen grief. May I not hope to have the aid of all our readers in making this department something that will be looked forward to, week by week, as precious to those who even may not longer have interest in the apiary?

A. J. Cook.

MAXIMS FOR THE HOME CIRCLE.

I copy the following from the "Intelligencer." I know nothing of this paper, its editor, or whereabouts, but I do know that if it has much like the following it is certainly rightly named. As I read over the following, "How to Make Happy Homes," the methodist in me (and I claim to have not a little) gave forth a most hearty "Amen." As I read it later about the "home circle," I found the "Amens" came twice-repeated.

1st.—"Learn to govern yourselves and to be gentle and patient."

What could we covet more wisely for our children than that they follow this maxim? The best way to secure this is to follow it ourselves. A man who kicks or strikes his cow is bequeathing to his children a very questionable heritage. I know a man who once moved, I think, as many as twenty times during a milking, and every time with a gentle "So, boss," and a more gentle press of the teat. The poor cow had a deep sore on the nipple. To have whipt and scolded would have been rank cruelty. Such an exhibition before a child would have been a grievous blunder. I know of a father who lived to be 85 years old. He was a fine example of physical energy and had an impetuous spirit, and yet tho I knew him very intimately, I never heard him utter a word that favored in the least of harshness to the dear, loving companion who was indeed a true helpmeet. I know a boy, tho hardly now a boy, for he is on the 30 side of the 20's, who tho he has the same spirit and temperament of the man just mentioned, yet I never knew him to lose his temper or show impatience. His parents told him as soon as he could understand that it was mainly to govern one's self. They acted their teachings as far as possible. Need I say that the result has made glad hearts?

2d.—"Guard your tempers, especially in seasons of ill health, irritation, and trouble, and soften them by prayer and a sense of your own shortcomings and errors. Remember that valuable as is the gift of speech, silence is often more valuable."

That is good advice. A home where such counsel prevails is a glad presence in any neighborhood. Who of us has not regretted with anguish of heart the angry word, or the irritated demeanor? How gladsome in the home is the temper that is ever controlled. How fortunate the one who can lay hold of silence when to speak is to wound. Even the bees resent the nervous, irritating mein.

3d.—"Do not expect too much from others, but remember that all have an evil nature whose development we

must expect, and that we should forbear and forgive, as we often desire forbearance and forgiveness ourselves."

I will only add to this Christ's incomparable words—"Father, forgive them for they know not what they do."

4th.—"Never retort a sharp or angry word. It is the second word that makes the quarrels." This is hardly more than the 1st and 2d. Government of self and temper controlled, will always stay the angry word. The quarrel is never manly, and we do well to remember that it always takes two to make one.

5th.—"Beware of the first disagreement."

What better advice than this could be given the twain who are just forming the home circle?

6th.—"Learn to speak in a gentle tone of voice." We can hardly understand how much seeming trifles like the voice-tone have to do with character. The description of Cordelia in Lear—"Her voice was gentle, soft, and low, an excellent thing in woman," is suggestive. A low tone, even in times of excitement, will generally effect more than bluster. Nervous and excitable children, especially, should be urged to gentle speech for it will surely bear fruit in character.

7th.—"Learn to say kind and pleasant things whenever opportunity offers." In other words, "Blessed are the peacemakers, for they shall be called the children of God."

8th.—Study the character of each and sympathize with all in their troubles, however small.

We may couple with this, "Inasmuch as ye have done it to one of the least of these, ye have done it unto me."

9th.—"Do not neglect little things if they can affect the comfort of others in the smallest degree."

Who has not seen homes that were constantly all aglow with little, thoughtful acts?

10th.—"Avoid moods and pets and fits of sulkiness."

If anything would convert us to the theory of the brute ancestry of man, it would be to see him in the sulks.

11th.—"Learn to deny yourself and prefer others."

This was the very essence of Christ's whole life and teachings.

12th.—"Beware of meddlers and tale-bearers."

I would add, Let us be very careful that we do not join their gruesome company.

13th.—"Never conceive a bad motive if a good one is conceivable."

Could we do otherwise if we obey the Golden Rule?

14th.—"Be gentle and firm with children."

I will add that if anything will keep a child in the right way it is that sacred thing—the mother-love. God pity the child who is bereft of it.

15th.—"Do not allow your children to be away from home at night without knowing where they are."

Is it not wise, also, to be with them ourselves? Their fullest confidence will prevent much mischief.

16th.—"Do not allow the children to go where they please on Sunday."

I know from a blessed experience that a home that is made to hold the children on Sunday will ever have their reverent gratitude. The home circle ought to keep the children at night and on Sunday.

17th.—"Don't furnish them with much spending money."

I have known many college boys ruined by a plethora of greenbacks. I have known many to be made magnificent men by the stringency of hard fortune. To the man who hands out money in fullest measure to his son, I would simply say, "Don't."

HELPFUL SUGGESTIONS REQUESTED.

I shall welcome hints for the home, recipes for table articles, and any other helpful suggestions.

BEE-KEEPERS' SUPPLIES

THE FINEST IN THE WORLD.

Our New 1901 Fifty-Two Page Catalog Ready.

Send for a copy. It is free.

G. B. LEWIS COMPANY....

WATERTOWN, WISCONSIN, U. S. A.

You Can't Afford to Guess

at results in the poultry business. If you fail to raise the chicks, you simply have no business to continue. You must first get the chicks to hatch, to employ a **Cyphers Incubator** in your hatchery. We guarantee them to last 10 years and to outlast any incubator made. The best way to know about it is to read our 252 page (1811 in) book, **"Profitable Poultry Keeping"**. Has 250 illustrations and covers the entire subject. We send it for 10 cents in stamps. Ask for book 50. Circulars mailed free. Address nearest office.

CYPHERS INCUBATOR CO. Chicago, Ill., Weyland, N. Y., Boston, Mass.

Please mention Bee Journal when writing.

Marshfield Manufacturing Company.

Our Specialty is making SECTIONS, and they are the best in the market. Wisconsin BASSWOOD is the right kind for them. We have a full line of BEE-SUPPLIES. Write for free illustrated catalog and price-list.

8A26t Marshfield Manufacturing Co., Marshfield, Wis.

Please mention Bee Journal when writing.

Queen-Clipping Device Free....

The MONETTE Queen-Clipping Device is a fine thing for use in catching and clipping Queens wings. We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year and the Clipping Device. Address:

GEORGE W. YORK & COMPANY, Chicago, Ill.

6A1f Mention the American Bee Journal.

WANTED.—A situation by a young married man, to assist in or care for apian, and fruit-growing. Experienced with bees; sober and reliable; handy with tools; small family and musician. N.Y. State preferred. Address, J. H. CLUTE, 432 Scotland St., Orange, N.J.

8A4t Mention the American Bee Journal.

Good Instruments.

Don't confuse these instruments with cheap "cheapen" others. They are high grade, fully guaranteed, instruments for \$1.00 to \$1.50.

VIOLIN—Amati model, choice of 3 colors, dark brown, light red or amber, full ebony trimmed, Brazil wood bow, pearl side, full leather bound canvas case, extra set of strings, rosin, etc., worth \$60. My Price \$6.25.

MANDOLIN—Solid Rosewood, standard neck, heavily bound canvas case, neck, celluloid front, ebony finger board, best quality patent head full leather bound canvas case. Regular price \$15. My Price \$7.65.

MANDOLIN—Solid Rosewood, 12 fret, celluloid front, veneered head piece, handomely mailed in elegant French carrying case, head, engraved tail-piece. Worth \$15. My Price, only \$7, with leather bound case, extra set of strings and tortoise pick. Send for circulars of high grade musical instruments of all kinds.

Charles A. Ball, the Auditorium, CHICAGO. Please mention Bee Journal when writing

TRACTION ENGINES

Should you be seeking the best thing in traction, portable and semi-portable engines, we have what you want. They are ideal for threshing, drilling wells, cutting and grinding feed, running saw mills, pumping water—anything requiring power. We have them.

From 8 to 20 H. P.

They all excel as quick, easy steers, require little fuel, remarkable strength, simplicity and durability. All boilers made of 60,000 lbs tensile strength steel plate. Fire boxes surrounded with water. Also Threshers, Horse Powers and Saw Mills. All fully described in our illustrated catalogue. Ask for it. Mailed free.

BIG CUT IN DRUGS

Direct to Consumers.

Our Handsome Catalog Free, costing over \$2 each, contains 144 pages, with 1500 illustrations and 1500 articles, and is so well guaranteed to save you from the drug store, the complete book of the kind. Sent for 10c to pay cost of mailing, which will be refunded with first order. Value of the reference letter will be sent to be in every household. Get it! Keep it handy.

Heller Chemical Co., Dept 13, Chicago.

The Only Mail Order Drug House in the World.

6A13t Please mention the Bee Journal.

Prospects Bright Losses by Fire.

The prospects for our bee-keepers appear to be much brighter than they were last season. We have had a pleasant winter, so far, not very warm and not very cold, and reports are that as a rule where bees went into winter quarters in fairly good condition they seem to be doing very well. The snowfall is heavy, and distributed thru the State, and it is still storming; this all insures a bountiful supply of irrigation water. The chances for a drouth the coming season are growing beautifully less each day.

I read the notice of your loss by fire with much regret. Some of our bee-keepers have been badly scorched, so that they know how to sympathize with you.

On May 1, 1896, I was awakened by a roar of fire, and got out just in time to see 50 colonies burned up in less than half that number of minutes. The fire was in a two-story lumber barn belonging to a neighbor.

I live on a lot 5x10 rods, with a street in front, and four close neighbors, and only five blocks from the business center of the city. Yet in 17 years I have never had a complaint, judging from the troubles of some of our bee-keepers, would indicate that difference in management. I have kept from 10 to 50 colonies each year. E. S. LOVET, Salt Lake Co., Utah, Feb. 20.

Bees in Fine Condition—Marketing Honey.

My bees are in fine condition, and I think they are going to winter without any loss, as they always have. I have lost but one colony since I began keeping bees; that was last winter, and I am ashamed to say that it was due to a leaky cover. In the last issue of *Gleanings in Bee-Culture* Editor York speaks of the small producer ruining the market by selling for less than the market price. That doesn't hit me, because I get 20 cents per section for my comb honey; the extracted I put up in pint Mason jars, and sell it at 30 cents a jar. JESSE M. DOXALSON, Worcester Co., Mass., Feb. 23.

Prospects Poor for Southern Indiana.

The thermometer has been at 10 degrees above zero for the past three days, after three weeks of mild spring weather, which started heavy brood-rearing in all colonies having plenty of stores. This will cause great losses to southern Indiana bee-keepers. The winter so far has been so open that most colonies have consumed nearly all of their stores.

There has been very little snow to protect the clovers, although sweet clover can stand the most exposure. I am experimenting with a large number of honey-producing plants. In the river bottoms I had an acre of sunflowers that gave lots of seed for the chickens, and the bees work on them continually last season. J. C. WALLEMEYER, Vanderburgh Co., Ind., Feb. 22.

Rendering Wax from Old Combs.

In rendering wax out of old combs I use the following method: Take the ball off of a 2-gallon tin pail with flaring sides, nail a stick about three feet long to the pail, so that it will project upward, then with a hammer and a 4-inch spike begin within two inches of the top to perforate the pail all the way around, and to within 3 inches of the bottom. Fill a big iron kettle about two-thirds full of combs and water (better soak them some, also break or chop them up). Hang the kettle in the yard, and start a good fire under it about sundown, if the bees are flying. After the mixture has boiled a while take the perforated pail and begin pushing it down into the melted

Maule's (35 new things for 1901) Seed Catalogue

You should, by all means, have this most modern catalogue of modern times. It is brimful and overflowing with good vegetable, farm and flower seeds, flowering plants, fruits, bulbs, etc. It contains 35 novelties in vegetables and flowers never offered before, has 100 large pictures, seven handsome colored plates and hundreds of illustrations. It gives practical, up-to-date cultural directions and offers many cash prizes. The first edition alone costs over \$30,000, so while we send it free to all customers, we must ask others to send 10 cents for it, which amount they may deduct from their first order. You will make a mistake if you do not write to-day for this the Novelties Seed Book of the year. Address:

WM. HENRY MAULE, Philadelphia.

mass with a circular motion (it will take some time to get the hang of it), and as the wax flows thru the perforations I use a tin cup, or something similar, to dip out the wax and pour it into a tub half full of cold water, to be eked up in the usual way later.

The beauty of this method lies in the fact that we can keep a good fire going and keep putting in combs and taking out wax, and to facilitate matters have a wash-bowl of hot water on the cook-stove, from which we can get warm water when needed, instead of using cold water. After too much refuse accumulates in the kettle, throw out the mass and begin with a new batch.

I melted the combs from 17 of my hives last season, besides working up those from 50 or 75 on shares. Those that we work on shares we melted in the woods near a pond, and used three kettles with fire under each.

Instead of there being 50 or 75 hives of combs I work up what was left from 30 to 45 colonies of bees. There were from 30 to 35 bushels of combs after they were stamped down in the wax-on-box. That put the perforated pail to a severe test, and it worked splendidly.

I don't think the different solar wax-extractors are to be compared with my method of rendering wax.

Marshall Co., Ind., Feb. 23.

Poor Seasons—Producing Extracted Honey.

I began the spring of 1900 with 100 colonies, and secured 2,800 pounds of surplus honey, about 500 of it being comb, but secured no increase in colonies.

We have had three poor honey seasons in succession, and bee keepers are blue, but I expect to hang on to the bees until the good seasons come again. The coming season will be my 21st one in bee-keeping. I have been a constant reader of the American Bee Journal for about 18 years, and consider it the best bee-paper published.

I notice that each of the expert bee-keepers allow the queen to roam around at her own sweet will, when working for extracted honey. My experience is that a first-class article of extracted honey can not be produced in this way, as pollen is sure to be stored around where the brood is reared, and this will cause the extracted honey to taste bee-bready (as we call it). This I know to be a fact here. From an experience of about 20 years in producing extracted honey, I claim that the place for the queen is in the brood nest, and I would have queen-excluders for this purpose, if they cost \$1.00 apiece. I don't want them when working for comb honey, as the queen seldom lays in the sections.

We should take as much pains to produce a No. 1 article of extracted honey as of comb, and in order to do this where much pollen is gathered we must keep the queen out of the surplus department.

Ashabula Co., Ohio, Feb. 8.

Southern California—Queenless Colony.

The old saying, "It never rains but it pours," comes nearly by verified in Southern California this winter. Up to the last of January it had as tho we were looking for an other dry season, at least in San Diego County, but it rained every day but one, from Feb. 1st to 10th, and the ground got such a soaking as it has not received in 3 years. And now all are rejoicing, for it is pretty certain that we will have good hay and grain crops, and when these crops are up we are sure of a good honey crop. It will also be a great benefit to orchards and vineyards—even to those that have water for irrigation in summer. We have had a few showers since the soaking, and vegetation is coming on rapidly. Bees are rearing brood, and they are bringing in more than enough honey to supply their needs. I have found 2 or 3 frames of new honey in some hives.

A friend who had a couple of colonies, did not care to keep them, so gave them to me, saying that if they stored any honey the coming season, I could give him what I thought was right. After setting them home I found

HONEY-SEEKERS' EXCURSIONS.

On the first and third Tuesdays of each month the Chicago, Milwaukee & St. Paul Railway will sell round-trip excursion tickets from Chicago, Milwaukee and other points on its line to a great many points in South Dakota, North Dakota, and other Western and Northwestern States at about one fare. Take a trip West and see the wonderful crops and what an amount of good land can be purchased for a little money. Further information as to rates, routes, prices of farm lands, etc., may be obtained by addressing F. A. Miller, General Passenger Agent, Chicago, Ill.

\$1,000.00 CASH

will be given to Subscribers of..... **Agricultural Epitomist** making the largest yield from one quart of "EPITOMIST PRIZE" White Dent Corn.

The prizes to be awarded in the following named amounts and paid December 1, 1910.

\$250.00 for largest yield \$400.00 for 10th largest yield \$100.00 for 71st largest yield
\$150.00 " 20 " \$25.00 " 30 " 50 prizes, \$5.00 each \$25.00
\$100.00 " 30 " \$15.00 " 60 " 100 prizes, \$2.50 each

MAKING A TOTAL OF \$1,000.00

Those contesting for one of these Prizes must send affidavit of yield with sample of corn, when mailing report; also report made of cultivation and fertilization.

ONE QUART "EPITOMIST PRIZE"

White Dent Corn with careful cultivation will grow enough seed to plant two hundred acres of land—200 ACRES.

This is a variety of corn of remarkable characteristics. It produced last year on the Epitomist Experiment Farm eighty bushels to the acre under exceedingly unfavorable conditions. The land on which it grew was of medium fertility only, the cut worms mowed it down, until there was, at one time, an intention of plowing it up, and, owing to natural conditions which we could not control, it received but one plowing. Corn that will produce eighty bushels to the acre under such conditions is exceptionally valuable. The length of the ears is from ten to twelve inches, the circumference is seven and a half inches and sometimes more; the cob is small and completely covered with grain; the grain will average a half inch in depth and same in width, and is unusually thick; the weight of grain and cob averages something over 30 pounds and there is over ninety per cent of grain. The "EPITOMIST PRIZE" WHITE DENT is an early variety that will mature anywhere where within the corn belt, and to those who appreciate the value of corn fodder, it recommends itself, as it produces a luxuriant growth of stalk, many of which in our field were fifteen feet high. It is certainly the best variety of corn that we have ever grown or seen grown, and there is every indication that it contains an unusual percentage of protein, and the higher the percentage of protein the more valuable the corn. We have never seen stock of all kinds that was fed almost exclusively on corn, do as well as one stock has done upon the Epitomist Farm.

The Epitomist Experiment Station,

is without doubt the most beautiful spot in the state of Indiana. Over \$100,000 has been spent in improvements on this Experiment Farm, where Agricultural Epitomist is edited and printed, and the activities of real farm life. Its beauty of scenery and perfect climate, with its pure spring waters, are hard to surpass in any other place. We have at this Experiment Station, all the different soils found in Indiana or anywhere else, and as well as the varied conditions of State, as well as the varied conditions of weather, including, etc., all to be included in our experiments which will be written up in the Epitomist from month to month. It is our purpose to give Epitomist readers some of the seed of this variety to raise, but \$1,000 in prizes for the same to be awarded as described above.

Every subscriber to the Epitomist is entitled to participate in this contest. All we require is that you send 50 cents for one year's subscription to the Epitomist and 50 cents to pay for postage, packing, etc.—50 cents all told. We will enter your subscription and send you one quart of "EPITOMIST PRIZE" WHITE DENT CORN by mail, postage prepaid.

THIS EAR OF CORN represents an average ear of "EPITOMIST PRIZE" WHITE DENT CORN and is taken from actual nature without tampering. The corn was grown the past season of 1910 on the Epitomist Experiment Station, and we feel that the remarkable results obtained justify us in expecting subscribers to derive much benefit therefrom.

Address **AGRICULTURAL EPITOMIST** Box 321
Epitomist Experiment Station, SPENCER, IND.
This Contest Is for EPITOMIST Subscribers Only.

Natural Size, 10 inches in length; 7 1/2 inches in circumference; weight, 17 ounces.

one colony queenless with queen-cells started. I thought it very doubtful if any queen would become fertilized at that time of the year (Dec. 17, as I had only two other colonies at home, and no drones to be found in any of them. (My apiary is 3 miles away.) In due course of time brood was sealed, but every one a drone, so I concluded that the next thing to do was to find a virgin queen, then the process of Nature might go on unhindered. In looking over another colony for eggs I found a frame with a queen-cell nearly ready to be capped, which I gave to the queenless colony after removing the drone-layer, and putting all frames containing eggs and brood into the other hive. In two days other queen-cells were started, then I put the drone-brood back and left them to work out their own family

affairs. Twenty-seven days from the time of putting in the frame of eggs, I opened the hive and found a queen with eggs in two frames, and plenty of drones. I expected to have a case of superseding in the hive from which I took the queen-cell, but yesterday I found plenty of eggs and brood, and concluding that her subjects had a greater reserve of vitality than her subjects gave her credit for.

F. C. WIGGANS.

San Diego Co., Calif., Feb. 20.

Using Chaff Cushions in Summer.

I have practiced leaving the chaff cushions on my hives all summer as well as winter, the last 6 or 7 years. I have tried both ways, and I find I gain at least 25 percent from the chaff-

covered hives. I have noticed in very hot weather the hives not covered with chaff would be nearly empty from 10:30 a.m. to 2:30 p.m., while those protected with chaff cushions, from 3 to 6 inches thick, would be apparently as full of bees as they could be and do their work.

My wife often says that I do too much experimenting, but I find it brings me the knowledge I am seeking for. There is no branch of bee-keeping in which I have not experimented. This is a progressive age, and I feel that we can do no too much to further the work of our industry. A. D. D. WOOD.

Ingham Co., Mich., Feb. 15.

Last Season a Failure.

My bees did very poorly last season, getting no surplus whatever. I hope for better things this year. C. H. DAVIDSON.

Caldwell Co., Mo., Feb. 19.

Bees Wintering Poorly.

I fear my bees are wintering badly. The weather has been very cold and windy here for about four weeks. We have had no rain since last November, and but little snow.

HENRY ALLEY.

Essex Co., Mass., Feb. 25.

Dispersing Robber Bees with Gunpowder.

I have been a keeper of bees since the early sixties, and it goes without saying that I have experienced the usual ups and downs common to the craft; also many of the pleasant (?) experiences, as, for instance, a bad case of robbing—in short, I have been "up against it" many times.

During all these years I have read many ways of stopping this trouble, in the current bee-literature of the times, but I have never seen mentioned a plan that I have often used with unflinching success. I learned it years before I kept bees, from my grandfather who often quoted disturbances with old-time and well-tried remedies. His plan was to "blow up" the robber-bees with gunpowder. About a tea-spoonful of powder is pushed into the entrance and then "touched off." I never knew this to fail but once, when I had an extremely bad case that had to be treated 3 times—the

last time with a charge of powder of sufficient force to lift the honey-board off of the top of an old-style Langstroth hive. Not the slightest injury was done to the combs, except that two or three of them were blackened a little at the extreme lower edge, and very, very few bees were killed—just the few that happened to be in the vicinity of the powder.

Some bee-keeper may hesitate to try such an energetic remedy, fearing to destroy or injure the colony, but he has no occasion for alarm, for he will do nothing of the kind. Gunpowder is a famous peacemaker among bipeds of the genus homo, and as the genus Apis seems to possess many traits common to man, why not employ the same means to settle their quarrels? With modern hives and large entrances I think a large charge of powder could be used without doing harm.

PEACEMAKER.

San Francisco Co., Calif., Feb. 18.

Experiences with Bumble-Bees.

I notice on page 108, Thomas Wallace gives his experience with bumble-bees. This is a matter to which I have given a great deal of attention. When I was a boy I had a great longing to have bumble-bees, and experiment with them, and often had as many as six to eight small colonies in little boxes and tin cans. I often watch them flying to and from their homes the same as other bees, and I tried wintering them by burying them, but never succeeded.

I used to pour a pailful of water on them in their nests to keep them under control so that I could have them, and closing everything up tight I would start for home and add another colony to my already started apary. I have succeeded in uniting all of my colonies, and found that the only way to do it without fighting was to smoke them (after first closing the hives) with penuryol until all were in an unconscious condition, then I would empty all the colonies onto the ground, place all the combs in one hive, pick the bumble-bees up with my fingers, and put them all into the hive containing the comb. By this time they were recovering from the effects of the smoke, and all was well. Each one seemed to think the other its "best friend and brother."

I tried to introduce the bumble-bee queens into colonies of our common honey-bees, but a fight was all I ever succeeded in bringing about, and all the way I ever received for my trouble was a pair of swollen eyes, and now and then a little fun. I would call the calves up close to the hives, then give them a few

sweet apples to attract their attention, then pour the bumble-bees with a long pole, and get these fierce bumble-bees to use their "swords" on the calves instead of me. But I wanted still more fun, so I finally succeeded in getting the doe close enough to get the bees after him, but I got even more fun than I had bargained for, as the king ran toward me, wanting me to share the pleasure with him, and he succeeded, for he ran after me, and I ran to keep away from him, but one of the bees got into my hair, and I had a time of it getting it out.

After several years' experience I concluded that I might as well drop the bumble-bees; still I shall not be satisfied until some one tries the plan of grafting larvae of the bumble-bee into queen-cells or cups of the common honey-bee, making the colony hopelessly queenless and broodless, or by transferring the eggs of the bumble-bee into the comb of the honey-bee. The egg of the bumble-bee is always sealed, also the larva, and there seems to be many different kinds of them—the worker, the queen, the drone, and there seems to be another "critter" among them.

The mating of queens is done toward the fall of the year, just outside of the nest, on the ground. All queens are reared in the latter part of the summer.

After all my experience with them I believe that if any bee is ever derived from them it must be brought about by a cross between them and the honey-bee.

P. W. STAHLMAN.

Albany Co., N. Y., Feb. 18.

Worst Season in 10 Years.

The season of 1900 was almost a total failure in this locality—the worst we have had in 10 years. Bees did not get enough honey for winter stores, and had to be fed.

We have had an open winter up to this month, and some zero weather, but not much snow.

W. D. HIGG.

Cass Co., Mo., Feb. 23.

YELLOW OR WHITE

Sweet Clover Seed

Free as a Premium

For Sending us One New Subscriber for a Year.

There has been so much written about both the white and the yellow variety of sweet clover, that we will simply say here that if one of our present regular subscribers will send us \$1 with a new name for this year, we will mail, postpaid, to the one sending the new name and the dollar, either one pound of yellow sweet clover seed, or two pounds of the white sweet clover. This is a good chance to get a start of both kinds of these honey clovers. Better send two new subscribers (with \$2.00) and get the three pounds of seed. Address,

GEORGE W. YORK & CO.

144 & 146 Erie Street, CHICAGO, ILL.

CONVENTION NOTICE.

Utah.—The Utah Bee-Keepers' Association will hold its regular spring meeting April 5th, at 10 o'clock a.m., in the City and County Building at Salt Lake City. All are cordially invited. We expect to get out a treatise or pamphlet, the object of which will be to give the best and quickest method to discover, cure, and prevent disease among the bees, and the best way to protect them from their enemies. It will also contain other matter for the benefit of the industry, including our State law. We will be pleased to receive communications from any of our bee-keepers upon any subject along the lines indicated. Address, Pres. E. S. LOVELL, Salt Lake City, Utah, or J. B. FAGO, Sec., East Mill Creek, Utah.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, March 8.—Fancy white comb sells readily at 16 cents, but all other grades are weak at the following range of prices: No. 1, white, 14@15¢; fancy amber, 12@13¢; fair amber grades, 10@11¢; buckwheat, fancy, 10¢; old grades, 8@9¢. Extracted white ranges from 7@8¢; buckwheat, 5@6¢; Southern dark, 5@6¢; amber grades, 4@5¢@7¢. Beeswax in demand at 30 cents.

R. A. BURNETT & Co.

KANSAS CITY, Feb. 19.—Fancy white comb, 16@16½¢; amber, 12@13¢; dark, 10¢. Extracted, light & amber, 7@8¢; buckwheat, 5@6¢. Extracted fair; receipts light. Beeswax, 22@24¢.

W. R. CROMWELL PRODUCE CO.,

Successors to C. C. Clemons & Co.

CINCINNATI, Feb. 9.—The market for comb honey is becoming very bare, although the prices have not changed. Fancy white comb is still selling for 16¢; no demand for darker grades. Extracted is in fair demand; dark sells for 5½¢; better grades from 6½¢@8¢; only white clover brings from 8½¢@9¢. Beeswax, 28¢.

C. H. W. WEBER.

ALBANY, N. Y., Feb. 11.—Honey market is dull and prices nominal; light stock, but the cold weather is bad for it. Comb, in good order, not candied, white, 15@16¢; mixt, 13@14¢; dark and buckwheat, 11@12¢. Extracted, white, 7@8¢; mixt, 6@6½¢; dark, 5@6¢.

H. R. WRIGHT.

BUFFALO, Mar. 7.—Fancy, 15@16¢; No. 1, 14@15¢; No. 2, 11@13¢; No. 3, etc., 8@10¢. Extracted, 8@9¢. Beeswax, 27@28¢.

All grades of honey selling fairly well, and looks as if all lots would clean up.

BATTERSON & Co.

BOSTON, Feb. 8.—Fancy No. 1 white in cartons, 17¢; A No. 1, 16¢; No. 1, 15@16¢, with a fairly good demand. Absolutely no call for dark honey. Extracted, white, 8@9¢; light amber, 7½¢@8¢. Beeswax, 27¢.

BLAKE, SCOTT & LEE.

NEW YORK, Feb. 19.—Comb honey is being well cleaned up on our market. The demand has lessened to quite an extent, on account, we presume, of the high prices which have been ruling. Fancy white still brings 15@16¢ in small way; No. 1 white, 13@14¢; amber, 11@12¢; buckwheat, 10¢. Extracted rather dull and not much doing. California white honey, 7½¢@8¢ a pound; light amber, 7¢; Southern, from 6¢ to 7¢ per gallon; buckwheat, 5¢@5½¢. Beeswax steady at 28¢.

HILDRETH & SROGELER.

DETROIT, Mar. 7.—Fancy white comb, 15@16¢; No. 1, 14@15¢; dark and amber, 10@13¢. Extracted, white, 8@9¢; amber, 7@8¢; dark, 6@7¢. Beeswax, 27@28¢.

M. H. HUNT & SON.

SAN FRANCISCO, Feb. 6.—White comb 13@14 cents; amber, 11@12¢; dark, 8@9¢. Extracted, white, 7½¢@8¢; light amber, 6½¢@7½¢; amber, 5½¢@6½¢. Beeswax, 26@28¢.

Considering the light output of honey last spring from California apiaries, present offerings are of tolerably liberal volume and are mostly of amber grades. The market is slow at the quotations. It is reported on good authority that adulterated and imitation honey is being dealt out in considerable quantity, which accounts in a great measure for the very limited business doing in the pure article.

HONEY MARKET.—We may have a customer within a short distance of you who wants your honey or beeswax. We advertise in every issue of all the markets; therefore write us regarding your crop, stating quantity, quality, and lowest cash price. References—Either Bank here for any business man in this city.

The Belgian Hare Guide

This book is acknowledged to be the finest and most reliable book out on the Belgian hare industry. It contains complete and practical information on the following and many other subjects pertaining to the industry: History and Origin, The Belgian for Utility, The Belgian for Fancy, The Business and How to Organize, Houses and Hutches, Foods and Feeding, Green Stuff, Mating and Breeding, Care of the Young, Hare Color, Dressing and Cooking, Belgian Remedies, Preparing for Exhibition, Crating and Shipping, Capitalizing, Queries and Answers, Miscellaneous, Belgian Hare vs. Poultry, The Belgian in England, The Belgian in California, Black Belgians and Poodles. It is elegantly printed on fine paper, illustrated with numerous beautiful photo engravings, and is substantially bound. No one interested in Belgians can afford to be without it. Send your order today. Price, 25 cents.

SPECIAL OFFERS.

For \$1.10 we will send the "Belgian Hare Guide" and the American Bee Journal for one year; or for \$2.00 we will send the Bee Journal for two years and the "Belgian Hare Guide."

\$200 Red=Clover Queen

Offer No. 35.

On September 1st last we announced that we finally had a red-clover
queen fully equal to the one we had years ago. The colony of this queen has
given one of the most remarkable showings on red clover of any bees we
have ever had. The queen in question is an imported one, and therefore of
the genuine pure leather-colored Italian stock. We sent out daughters from
her all the season. But we did not discover her value until the clover season,
second growth, came on, and then her colony so out-distanced all the other
450 that she attracted attention at once.

It must be understood that these queens are not golden yellow, neither
are their bees of the five-banded stock. They are simply leather-colored Ital-
ians whose mother came direct from Italy.

Since the notice appeared regarding this queen we have hardly been able
to supply all of the queens that were wanted from this stock. Many daugh-
ters of this queen we sent out before we knew her value, and it now transpires
that some of the finest bees in the land are from queens we sent out
early. We are now booking orders for the coming season, and make the fol-
lowing offer, but no queens will be furnished except those that subscribe for
cleanings, and only one with each year's subscription. All arrearages must
be paid to the end of this year. Cleanings for 1901 and one untested red-
clover queen, \$2.00; Cleanings one year and a tested red-clover queen, \$4.00;
a select tested red-clover queen and Cleanings one year for \$6.00. We will
begin mailing these queens in June, 1901. Orders are already entered, and
the same will be filled in rotation. Do not neglect to improve this oppor-
tunity and get some choice stock, and send your order early so you may get
the queen correspondingly early in the season. We are using every precau-
tion to winter this queen safely, but reserve the right in case of her loss this
winter to substitute from other select tested stock of this strain which we are
holding in reserve, or to give the subscriber the benefit of any of our other
clubbing offers if desired.

FORTY-FIRST YEAR
No. 12.

WEEKLY

Tent for Controlling the Mating of Queens.
(See page 181.)

Courtesy Bee-Keepers' Review.

PUBLISHED WEEKLY BY

GEORGE W. YORK & CO.

144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, 50c a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

Reformed Spelling—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

National Bee-Keepers' Association

OBJECTS:

To promote and protect the interests of its members.

To prevent the adulteration of honey.
To prosecute dishonest honey commission-men.

The Bee-Keeper's Guide:

Or, Manual of the Apiary.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without *THE BEE-KEEPER'S GUIDE*.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers for the way of getting new subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year.

Send us two NEW SUBSCRIBERS to the Bee Journal with \$2.00, and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO new SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street,

CHICAGO, ILL.

Long-Tongued Bees

ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2; or, one Tested Queen free as a premium for sending us FOUR new subscribers (with \$4.00.)

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation—"first come, first served"—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipt, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

28 cents Cash
paid for Beeswax.

*** This is a good time
*** to send in your Bees-
*** wax. We are paying
*** 28 cents a pound—
*** CASH—for best yel-

low, upon its receipt, or 30 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO.

Best White Alfalfa or Basswood Extracted Honey

ALL IN 60-POUND TIN CANS.

ALFALFA
HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD
HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are boxt.

Order the Above Honey and then Sell it.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

ESTABLISHED IN 1861 AMERICAN THE OLDEST BEE-PAPER IN AMERICA BEE JOURNAL

41st YEAR.

CHICAGO, ILL., MARCH 21, 1901.

No. 12.

* Editorial Comments. *

Large Yields of Honey.—Mr. Frank Benton says: "Mr. Doolittle is mistaken regarding what he says in the last four or five lines over his name, on page 147. Cyprian bees were sent to America in 1880. The yield of 1,000 pounds, in 1881 or 1882, in Texas, was by B. F. Carroll, from Cyprians I sent over."

Honey Prospects in Southern California.—Prof. A. J. Cook, of Los Angeles Co., Calif., writing us March 8th, had this to say regarding the prospects for a honey crop:

"The bee-keepers all thru southern California are pleased with the prospects for the coming season. We have had a generous rainfall, and may assuredly expect a bountiful honey crop. The State and three county associations have held meetings within a few days. All are rejoicingly expectant."

Bee-Glue or Propolis in Paint.—Dr. J. M. Ross, of Clearfield Co., Pa., wrote us as follows recently:

EDITOR YORK:—Enclosed find two samples of painting from bee-glue colored with dry paint—bee-glue dissolved in wood-alcohol. I believe it will stand the weather better than oil paints.

(Dr.) J. M. ROSS.

This is decidedly interesting, and perhaps well worth following up. The paint seems to have a fair body, and is with difficulty scraped off the wood. It is possible, and indeed probable, that for some purposes, at least, this paint may be ahead of other paints. If so, there is a possibility of a boom for Tunisian bees. At any rate, if propolis should become a merchantable article, the scraping it off will not be considered the same drudgery that it now is.

Bee-Keeping Within City Limits.—Last week we received the following from Mr. J. C. Wallenmeyer, of Vanderburgh Co., Ind.:

EDITOR AMERICAN BEE JOURNAL:—A bee-keeper of Evansville—Mr. Buhrner—was fined \$5 and costs, March 6th, for violating a city ordinance, which forbids the keeping of bees in the city, or one-half mile from the city limits. The ordinance went into effect Jan. 1st, and many bee-keepers delayed moving their bees until they saw whether the city authorities intended to enforce the ordinance. The passing of the ordinance was a result of Mr. J. J. Cosby's bees soiling his neighbor's washings, when taking cleansing flights, and also stinging a horse, altho he made good all the damage done. The above suit was brought about by a relative, who got the worst of a will, and so took advantage of the bee-ordinance to retaliate. More suits to follow.

J. C. WALLENMEYER.

Upon receipt of the above communication we wondered how many bee-keepers in and about Evansville are members of the National Bee-Keepers' Association. If they are not already members they should join at once, before getting into any further trouble.

We would like to suggest that the Board of Directors of the Association look into this matter, and see what they can do to have the city ordinance declared null and void. We see no reason why such should not be done, and done immediately. There is no reason why bees should not be kept within the limits of any city on the globe. Of course, there may be special cases where they might possibly become troublesome, but any reasonable bee-keeper would not continue to keep bees where they were a source of real annoyance to his neighbors.

There are many small apiaries in quite thickly settled portions of Chicago, and there are also a number of quite large apiaries further

out, but yet within the city limits. So far as we know, they cause no real trouble to any one, while they are a source of considerable revenue and enjoyment to those who own them.

We hope Mr. Wallenmeyer will take up this subject with General Manager Secor, with a view to seeing what can be done to put an end to the "more suits to follow."

The "Cotton" Controllable Bee-Hive Fraud.—Mr. C. S. Blake, of Middlesex Co., Mass., has sent us the annual circular for 1901 of "The Controllable Bee-Hive and New System of Bee-Keeping," invented by Mrs. Lizzie E. Cotton, about 1878, now owned by C. B. Cotton. Referring to it, Mr. Blake says:

"It must be all fraud. Would it not be well to expose it in the American Bee Journal? Some 23 years ago a lot of us were bitten by this same Lizzie E. Cotton, now under the name of C. B. Cotton."

Yes, it may be well once more to occupy a little of our space in warning bee-keepers against this old fraud. In 1897, one of our subscribers sent us a similar circular dated 1896. In it we found a testimonial which reads as follows:

Hon. Robert W. Furnas, Governor of Nebraska, says:

Having used the "New System of Bee-Keeping" and found it a success, I recommend it cheerfully to others.

ROBERT W. FURNAS.

Upon receipt of the circular we immediately wrote to the Hon. Mr. Furnas, under date of April 26, 1897, saying that we had noticed his testimonial in a circular sent out by Cotton, and asked him to let us know the extent of his experience with the "Cotton" hive and system; also, whether he still recommended it. The following is his reply:

BROWNVILLE, NEBR., April 29, 1897.

GEORGE W. YORK & Co.

Sirs: I have no remembrance of giving the testimonial referred to. Nor do I call to mind "The New System of Bee-Keeping" named.

Very truly,

ROBERT W. FURNAS.

There you have pretty good proof of the fraudulent character of the cotton outfit, and all bee-keepers will do well to beware of it.

With the cotton circular of 1896 there was offered a full colony of Italian bees in the "Controllable Hive" (6 movable frames), with full set of 5 one-pound boxes with starters of foundation, feeders ready for feeding, and also a book giving full instructions how to manage bees by the wonderful new Cotton system of bee-keeping! This whole outfit was offered for only \$30, f. o. b., the express office in the State of Maine!

In the 1901 circular we find the entire outfit is offered for \$6, and 35 boxes instead of 5 are included with each hive. This is getting down more nearly to business in price, but the inducements held out to prospective bee-keepers to invest are somewhat remarkable. For instance, read the following paragraph:

"Two of the largest yields of box-honey I ever obtained, and which I think hard to excel, were as follows, viz.: 1 selected one of my best swarms in early spring; I fed them and treated them with the object of obtaining the greatest possible yield of box-honey. I arranged to have no increase in number of swarms, but to employ all the bees storing honey in the boxes. They gave me a little over 350 pounds of nice honey in boxes. Another, a young swarm, lived in the Controllable Hive July 1st, yielded in 10 days one hundred and four pounds of nice honey in boxes."

Our Cotton friend also has the following paragraph in his circular, referring to "bee-journals and other publications," which is quite interesting:

Beware of counterfeits.

Please remember, if you want the Controllable Hive with book, giving full instructions for the management of bees, send your order direct to me. Beware of that class who are slandering and lying against me and the Controllable Hive. They do this thru the *bee-journals* and other publications that they are *control*; believe them not. They are

interested in some *patent* or *non-patent* or *worthless* *hive* or *fixtures*, and are broiling over with wrath against me, because the Controllable Hive is steadily gaining in the estimation of all honest bee-keepers, and the demand for the thousand patent and non-patent *worthless* *hives* is steadily on the decrease. *A word to the wise is sufficient.*

We think further comment is hardly necessary, as no reader of any of the present-day bee-papers would be caught by the successor of the fraudulent "Lizzie." It is pretty safe to put it down as a rule that when too much is claimed for a particular hive—especially if the beautiful word "controllable" is emphasized rather strongly—the whole outfit is a pretty good thing to let alone.

* The Weekly Budget. *

HON. EUGENE SECOR helped to entertain the Upper Des Moines Editorial Association, Feb. 15th, at Forest City, Iowa—his home town. From the local newspaper reports they had a jolly time. Mr. Secor gave a reply to a toast, and of course did it in rhyme, something after the Will Carleton style. If it weren't so long we would reprint it, and to make extracts from it would spoil it. Mr. Secor knows how to entertain, and also how to "jolly 'em up" with his poetical pen.

MR. D. H. MERCALF, of Calhoun Co., Mich., writes us that in his article on page 158 we made him say that he "hunts bees for a living." This must be quite an error, as he says that every pound of honey he gets out of a bee-tree *costs* him \$1.00! The fact is, he puts in his leisure time and vacations in hunting bees. He says, however, that we may possibly be correct, after all, as to his hunting bees for a living, as he believes it has prolonged his life, every bee-hunt giving him renewed health and strength.

ANNIVERSARIES AND BIRTHDAYS.—Recently we received the following from a reader who signs himself "Old Fogey":

MR. EDITOR: I've become used to your new-fangled way of spelling, and rather like it, but I don't know about your reform in the *measurement* of words.—Do Rev. A. B. Mettler and you guess (32) mean by your say so? He was born Feb. 1, 1844, and you say each Feb. 1st since then was an anniversary. The dictionary says such an anniversary is a birthday, and according to that he has had a lot of birthdays, and the first day of next February will also be his birthday whether he is then alive or not. Now, what do you say? Shall we go by the dictionary or take the Mettler-York plan? OLD FOGEY.

Seeing this is mostly Mr. Mettler's funeral—"or birthday" we'll let him wiggle out first.

MR. W. A. PHYL, of Alameda Co., Calif., wrote us as follows, March 19th:

MY DEAR MR. YORK: You have no doubt been fully informed about the splendid rainfalls we have had in this [central] part of the state. They have been abundant. For about two weeks up to last night, the weather was fine. At the latter time, without any warning to mention, rain set in again and fell copiously thru the night and a portion of the day. The prospects are good for still more.

There is already an abundant supply of flowers. In some places the hills and the fields in the lowlands are yellow with honey-producing flowers. This is saying nothing of countless other flowers that are in bloom, which includes the Australian blue-gum, acacias, willows, alfalfa, etc.

Out by the side of the Pacific Ocean, whither I go when I have the time, an electric car line a step from in front of our office runs direct to Old Pacific in about 40 minutes, and on the very edge of the ocean I find an abundance of honey-secreting flowers. Over home, where I was a week ago, I found my bees working with a will. Some colonies were on the point of swarming. As the apary had not the attention last year that I used to give it when living on the old home-stead, I found that some of the colonies had gone the way that bees are apt to go when not properly looked after. It may be possible that I may soon be able to give them some attention again. I like to look after them.

W. A. PHYL.

Please send us Names of Bee-Keepers who do not now get the American Bee Journal, and we will send them sample copies. Then you can very likely afterward get their subscriptions, for which work we offer valuable premiums in nearly every number of this journal. You can aid much by sending in the names and addresses when writing us on other matters.

Contributed Articles.

No. 1.—Drone-Bees and Their Utility.

Can We, and Shall We, Control Their Production?

BY C. F. DADANT.

THE discussion on the utility of the drones in the hive under domestication, which was considered at length at the Paris Congress, has led to the expression of opinions from several bee-keepers in different publications on this subject, and I have concluded to bring the matter before the readers of the American Bee Journal with the hope that it may lead to further investigations and experiments. It is my intention, if permitted, to explain the subject at length, so that even beginners may see and understand the importance of the proposition set forth. So I will expect to develop the matter in two or more articles.

That the drone is an idler we all know, even those who have but a very faint knowledge of his physiology, for the name "drone" is proverbial as designating a useless being. As early as the beginning of the seventeenth century, Butler, (a writer on agriculture and bees), described the male bee as "a gross, stingless bee, that spendeth his time in gluttony and idleness. . . . worketh not at all, either at home or abroad, and yet spendeth as much as two laborers." We all know that the drone flies out only when the sun is high and the weather warm; that he does not go out in search of honey, never goes into a blossom, but only roams about for pleasure, and always comes home to eat. We also know that he occupies a great deal more room in the hive than his sister, the worker-bee, for the cells in which the drones hatch measure four to the inch, while the worker-cells measure five to the inch. Thus one square inch of worker-comb can hatch between 53 and 55 workers, while a square inch of drone-comb can contain only some 3drones. Alvaro Butler said that they eat as much as two of the workers, it is not likely that they spend so much, but it is probable that it costs as much food to rear and hatch the drones in a square foot of comb as it costs to hatch the workers that occupy the same space. This looks to me quite a reasonable presumption, and in the absence of actual evidence we can take it for granted that 5,000 drones cost as much food to become perfect insects as 7,500 workers would cost.

In his physiology the drone shows the purpose for which he is made, by the differences existing between him and the other inhabitants of the hive. Aside from the difference in the sexual organs, the drone shows a much greater power of vision by the extraordinary number of facets in his compound eyes, numbering, according to Cheshire, as many as 13,000 on each side of the head, while the facets of the composite eye of the worker-bee number only about 6,300. It is evident that the purpose of this extraordinary vision is for the finding of the young queen while on the wing, since it is of great importance that she should be enabled to meet with a drone at her first flight, for the life of the colony usually depends upon her successful mating and prompt return. It is certainly also for this reason that so many drones are reared in the hives during the swarming season. If only half a dozen or so of drones were reared, it would be very difficult for the queen to find one of them, and several repeated flights for this purpose would endanger her life the more. But the drone plainly shows that he was not born for work, by the shape of his legs, which have none of the pollen-baskets that serve the worker-bee in bringing a load home, and by the shortness of his tongue. His proboscis is not made to lap honey out of the blossoms, but only to suck it out of the store-cell, so the poor fellow is surely not to blame if he is lazy and worthless. He only follows his destiny. But his faculty for flight is remarkable, since altho his bulk is only one half more than that of the worker, his wing-area is to that of the worker as nine is to five. This is another instance of his adaptability to the purpose of his existence. The mating with the queen taking place only in full flight, it is necessary that he should be able to overtake her, and the natural law of intermixture between different families

makes it imperative that the mating should be between queen and drones of different colonies.

A short flight on the part of both queen and drone would lead to the probable mating of inhabitants of the same hive—brother and sister—and Nature carefully avoids this in all beings.

The natural, instinctive knowledge of the necessity of having drones in the hive at some seasons, is very strongly marked in the worker-bee. Drones are rarely kept over winter in normal conditions—they are usually killed, or driven away at the end of the harvest, yet we all know that if a colony remains queenless, its bees will not only fail to kill their drones at the beginning of winter, but will even accept drones which have been driven out of other hives. This I know from personal experience, for I have seen Italian drones, late in the fall in a queenless hive which contained only black bees. These drones could not have been reared there, but had evidently come to it when driven from their home, and the bees, altho having no possible use for them, had accepted them. It is plain, that realizing the need of a queen, and vainly in hope of securing one, they keep the drones with them in the expectation that they may be needed. It is in part also for this same reason that a queenless colony builds only drone-comb.

Unless a queen is old, or unhealthy, or unfertilized, she will not lay drone-eggs until the colony is already well supplied with worker-bees and brood. She will pass over drone-comb, and carefully select only such cells as are suitable for worker-bees. This shows conclusively that she does not like to lay eggs in drone-cells. As her eggs are fertilized in passing out of her oviduct, and only when they are to be worker-bees and are laid in worker-cells, it is quite probable that she finds more pleasure in laying these than in laying the drone-eggs, which microscopists tell us pass out of her body without being fertilized at all.

This ability on the part of a female insect to lay eggs that will hatch altho unimpregnated, was discovered in the honey-bee by the famous Dzierzon, and has long been disputed as incorrect. It is called "parthenogenesis."

But when she has been laying a great number of worker-eggs, the queen very probably becomes tired of the function, and as the eggs keep coming she seeks rest by hunting for larger cells and laying drone-eggs. This would explain why, at certain times, she will hunt for drone-cells. As a matter of course these likes and dislikes of the queen are all presumptions, but the evidence is very favorable to the views we take, and even slight circumstantial evidences lead to the same conclusion. For instance, a young queen that is healthy and vigorous, will lay a much less number of drone-eggs than an old queen. She evidently feels well and enjoys it. That a queen can not usually lay worker-eggs in drone-combs was evidenced by an experiment made by a Mr. Drory, of Bordeaux, France, some 20 years ago. A swarm was supplied with nothing but drone-combs. For quite a number of days no eggs were laid except a few drone-eggs, and finally the worker-bees reduced the outer opening of a number of drone-cells so as to narrow them down to the size of worker-cells, and the queen laid a few eggs in them.

In my next I will consider the reasons which cause worker-bees to build a greater or lesser proportion of drone-comb in the hive.

(To be continued.)

The Mating of Queens in Confinement.

BY J. S. DAVITTE.

REPLYING to an inquiry as to how I got queens mated in confinement, I will say that I built a large tent, 30 feet in diameter and 30 feet high, the covering being of mosquito-netting. Colonies of bees well supplied with drones were placed close up against the wall of the tent, on the outside, each colony being allowed two entrances. One entrance opened outside of the tent, and was contracted so that neither queens nor drones could pass, but allowed the workers to pass out and in, and work in the fields in the usual manner. The other entrance opened into the tent, and was large enough for the passage of a queen or drone; but it was kept closed or darkened for about a week after the colony was placed in position. This was done for the purpose of educating the workers to use the outside entrance. The drones were not allowed to use the outer entrance at any time, nor to enter the tent except from 11:00 a. m. until 1:30 p. m. After the drones had learned the

bounds of the tent, they seemed contented, and made a very pretty "school" flying in the top of the tent.

And I wish to say right here that the *drones* are the main feature of this problem. Once you get them *quiet and reconciled* to fly in the top of the tent, the problem is solved. Nine times out of ten the queen will not reach the top of the tent before receiving the most prompt and gushing attention.

After I got the drones under control I had no difficulty. I simply turned in the queens from the hives they were in, just the same as I turned in the drones. One year reared about 100 queens and had them mated in this tent. A queen would leave the mouth of the hive, and return in about five minutes, apparently mated; and in three or four days would be laying; and the progeny of all queens thus mated showed the same markings as the workers of the colonies from which the drones were taken.

The workers seem to be more annoyed than the drones when they find themselves confined in the tent; and I aim to keep them out of the tent as much as possible by not opening the tent-entrance until nearly noon, when most of the workers are in the field. As a further precaution, the tent-entrance is kept shaded or darkened.

The queens are not turned in until the drones appear to be well satisfied with the bounds of the tent; and when they are in this condition I believe that 500 queens a day might be mated in such a tent. Where queen-rearing is carried on upon a larger scale, I believe that this plan would be preferable to the open air; as I have seen a young queen leave the hive, in the open air, as many as three times, and be gone 15 minutes each trip, returning at last unmated.

My plan for queen-rearing is as follows: I choose a choice colony from which I wish to rear my queens; and from this colony I remove the queen, and allow the bees to build queen-cells. At the same time I make queenless such colonies as I wish to break up into nuclei. Two days before the queens will hatch, I form my nuclei, cutting out and destroying all cells, and arranging the nuclei around the bottom of the mating tent. The queen-cells from the choice stock are then cut out and given to the nuclei, the outer entrances contracted so that no queen can pass, and the inner entrances closed entirely. After the young queens are two or three days old, I open the tent entrances at 11:00 a. m., and leave them open until 1:30 p. m., each day, for several days, or until the queens are mated.

Now for the drones: At the same time that I remove the queen from the choice stock for the purpose of securing queen-cells, I place several hives that are strong with select drones around the walls of my tent, with the outer entrances contracted, as already explained, so that no queens or drones can pass, and, at 11:00 o'clock each day I open the inner entrance and leave it open until 1:30. With this daily exercise in the tent for 16 days, I have my drones tamed, or accustomed to their surroundings, or under control, so to speak; and it would interest a bee-keeper to take his place inside the tent at noon, and see the ladies meet the gentlemen, who, Barkis-like, are "willin." I have seen the mating take place before the queen could reach the top of the tent. Before they separate, the queen and drone fall nearly to the ground, and the queen goes directly to her home that she left not three minutes before.

If I were to build another mating-tent, I should build it about as follows: I would secure 12 tall poles. I would have them at least 30 feet long—40 would be better. These I would plant firmly in the ground, 12 feet apart in a circle. From pole to pole, at the top, I would stretch No. 10 wire to keep the poles true and in place. I would also brace the poles from the inside; and the braces would be allowed to go up 20 feet on the inside, as the drones use only the upper part of the tent. At the top of the poles I would also stretch No. 10 wire from each pole to its opposite neighbor, thus strengthening the structure and furnishing support for the covering that goes over the top. I strengthen every seam of my netting by stitching on a strip of bridle-rein stuff about an inch in width. This allows me to stretch the covering very even and tight without tearing it. Common boards can be used around the bottom to the height of five or six feet. At noon the tent should have the appearance of a sun-palace. Bee-Keepers' Review.

Polk Co., Ga., Jan. 22, 1901.

[Editor Hutchinson has this comment on the subject of mating queens in confinement. EDITOR.]

In taking up this subject, perhaps some of my readers will think that I am foolish, or visionary, or chasing an

ignis-fatuus. If you wish to see a bee-keeper draw up the corners of his mouth, mention this subject. When this subject was first brought up it was looked upon in all seriousness. Of late it is mentioned only with ridicule. The man who would propose to accomplish anything practical in this line would be clast with the man who is trying to invent perpetual motion.

Seriously, is it wise to discourage attempts in this direction? There is no doubt that there is as much difference in bees as there is in other domestic animals; and the one thing needful to enable us to develop strains of bees superior to those that we now possess, is control of the mating of the queens. Where would our short-horns, Jerseys, Merinos, Poland Chinas and Plymouth Rocks be now if the mating of these animals had been no more under our control than is the mating of our queen-bees? The next great step that we ought to take in apiculture is that of securing control of the mating of the queens. It is of sufficient importance to deserve much careful experimentation.

A Mr. LaVae, of Florida, wrote me that he thought queen-breeders might do away with the sending out of so many mated queens if they would have them mated in confinement. I replied in the usual strain that it had been tried and abandoned as a hopeless task. I askt him to let me know who had ever tried it, and made a practical success of it. He gave me the name of Mr. J. S. Davitte, of Georgia. I entered into correspondence with him, and from this correspondence I have gathered, arranged and condensed his article. The reading of the letters from Mr. Davitte aroused my interest to the highest point. He writes in such a way, and gives details so thoroly, that he has convinced me of his success.

I have spent considerable time in looking up and reading everything that I could find upon this subject. As I look at it now, the principal trouble has been that the drones have not been brought under control. When a drone has been accustomed to soar away thru the blue ether for miles and miles, he is not going to be shut up in a little 30-foot tent and be contented. For a long time, at least, he is going to spend all of his time in trying to get out. He is in no mood to pay his addresses to a queen. Catch two wild birds at mating-season, and shut them in a cage. Do you suppose they would mate? Canaries have been kept in captivity for many years, and they readily mate in a cage. Mr. Davitte had his drones flying for days in his tent before any queens were released in the tent. Perhaps many of those drones had never flown in the outside air—knew nothing of it. Having flown for several days in the tent they became accustomed to that kind of flight, were in a normal condition, and ready to mate with a queen should one appear.

Suppose we could make a cage two miles wide and half a mile high. Is there any doubt that a queen would be mated inside such a tent? Suppose it were reduced to one mile in width, and one-fourth of a mile high. Don't you suppose it would be a success? The question then is: How small can it be and still be a success? My opinion is that the size is not so very material as it is to get the drones to fly and *feel at home*. One large enough for that is, in my opinion, large enough. Mr. Davitte, who has had experience, puts it at about 50 feet in width and 30 to 40 feet in height.

There is still one more point: Not all drones, at all ages, are capable of fertilizing a queen. Many have failed from not understanding this point. They have put nuclei, with young queens, into a tent, then caught drones at haphazard and put them into the tent. Some of them may have been youngsters, just out of their cradles, so to speak. Others may have been "old greybeards." All of them would certainly have been frightened out of their wits to be caught and shut up in a tent away from their home. I think that Mr. Davitte has found the key that will unlock the problem, viz: That of getting drones from a normal colony, that is, working undisturbed in the open air, to fly *unworried* inside an enclosure.

If I had the time, money, bees and opportunity, I should certainly build a mating-tent another season and test the matter to my own satisfaction. By the way, this is the work for an experiment station. To be sure, Prof. McClain did try this experiment, but the conditions were such as to make it of small value. The queen-breeder who will build such a tent, and succeed with it, will certainly have one of the biggest advertisements that could possibly be secured for a queen-breeder. I wish that some one who is in position to make the experiment would build such a tent and give the matter a fair trial. Even if it should not prove to be the brilliant success that is reported by Mr. Davitte, it

might be a start, or a beginning of something that would eventually lead to success.

Don't let us lose our heads with enthusiasm, nor toss the matter aside with contempt and ridicule. With the new light that we now have on the subject, let us give it careful, thoro trial, standing ready to meet either failure or success.

Can Almost Any One Keep Bees?

BY A. C. SANFORD.

WH(0) may keep bees? The professional certainly may because he knows all the ups and downs, the crooks and turns, the successes and losses, and knows how to make the best of them. But the many who would like to keep a few colonies in order to get a family supply of the delicious and wholesome God-given sweet, lack the experience that often costs much, and is therefore valuable. Almost any one can learn how to manage the swarming, and how and when to put on supers; and, last but not least comes the wintering problem. Most Northern bee-keepers prefer to winter their bees in the cellar or a cave, as it takes far less honey and is generally the most successful plan—at least in Wisconsin. In these days we have text-books on bee-culture and all the science and mysteries of the honey-bee may be learned, but the actual practice and experience is another thing.

I well remember my experience with the first colony of bees I ever had. It swarmed only once, then the parent colony became destitute of a queen. I told a neighbor that I thought something was wrong, but he thought not because the bees were carrying in pollen. Later I found that the queen had an imperfect wing, had never met a drone, and produced only drone-eggs, so I lost the colony. The following spring I purchased a few colonies in box-hives, and transferred them into movable-frame hives. It was then I first attempted to make a swarm by dividing, and the bees swarmed out; but I soon learned a great many things and made the bees pay.

Many people would keep bees if they were not afraid of the stings. Of course there are some to whom the sting of a bee is poisonous, and they will do well to let bees alone. But such people are few, and if one intends to keep bees he must make up his mind that he is going to endure the stings, and in due time his system will get used to them. The pain may be relieved with wet salt, hartshorn, mud, etc., or by quickly pulling out the sting. If one is careful he is not likely to get very many stings, but if he thinks that he never will be stung he is very much mistaken.

Two very essential things in handling bees are a bee-veil and a first-class smoker, with an ample supply of smoke-making material. Smoke is a great protection, and if the bees fly about you angrily give them a generous dose.

Women-folks can learn to care for bees as easily as they do for chickens, if they only have the courage and the pluck. It is much easier to learn to keep bees than it is to learn to play the piano. And then think of the delicious honey you will have to sell and to eat!

Pierce Co., Wis.

A South Dakota Bee-Keeper and His Little Apiary.

MR. EDITOR: Being a reader of The American Bee Journal, I presume you would like to hear something about how one of its pupils is getting along. I was just on the meridian line (in age) when the bee-fever struck me, having spent most of my life in Chicago, and other cities. I am sorry now that I did not start keeping bees 25 years earlier. When I came out here I told my neighbor (an old bee-master) that I intended to keep bees, and he told me that they might live all right providing I would feed them all summer and give them enough in the fall to last them all winter. Happy the man who thus expects but little, for he will never be disappointed.

I found out that this is a very poor country in which to keep bees, for we have little timber, no clover, or any other honey-plants that amount to anything. We have dwarf sunflowers in abundance, and they furnish a little honey of an inferior grade. Sweet clover grows tall if irrigated, but on waste land or on the roadsides it doesn't thrive. I tried buckwheat, but the bees did not work on it, and, besides all this, the wind blows here sometimes so furiously that if the hive-entrances were the size of a stovepipe the bees would hardly be able to reach them.

This experience has not taken the bee-fever out of me, but it caused me to move to a more favorable locality. I think bee-keeping is the most healthy and pleasant occupation in the world, and it is enough to make me shudder when I think back, of city life, where some of you folks are working under a gas-jet in dimly lighted rooms or basements; or how I used to grab my hat and coat at noontime, make a rush for the street, jump past the coming street-car, and make a break for the restaurant to swallow my lunch and get back again to get out this or that order. Yes, a feeling comes over me like a nightmare, when I think of watching for that ball on the Masonic Temple to drop, and set my watch by it so as not to miss the suburban train in the morning. But the bee-keeper looks for the sun to turn around the gable, which is near enough for him to tell that it is noon; and when you city folks are hustling and bustling in smoldering basements, the bee-keeper, surrounded by birds and vegetation, works in his garden, from where he can watch his bees, or else fans himself under a shade-tree and waits for swarms.

To return to my bees, I will say that I have "A B C of Bee-Culture," Langstroth, and Prof. Cook's Manual, as my guides, and the extent to which I appreciate the American Bee Journal is shown in the accompanying photograph, where it is represented by a wheel (or "journal.")

Being a mechanic I was bound to make my own hives, altho they cost me as much for material as the price I could buy good chaff hives for. My neighbor calls them "dandies," and says they are the finest hives he ever saw. I am ready to admit that this credit is not altogether due to me, for they are but a combination of other people's brains. The general shape was taken from Root's, the portico from Langstroth's, and the telescope feature of the body over the bottom was taken from Dadant's, which enables me to put a frame between the body and filled chaff bottom for wintering. For the pattern of the observation hive I have to thank Prof. Cook.

The rocks or boulders at the side of the hives are not put there as an ornament or bee-mark, but they are sometimes needed in this part of the country to pile on top the hives so as to keep them attach to the world, or not to find them some morning in your neighbor's field mixt up with cornstalks and Russian thistles.

I am very much interested in the different ways bee-keepers introduce queens, and no sooner have I come to a conclusion than I see that manner criticized in another paper. I think this criticizing or debate is the proper way to learn, but it strikes me that some of our more experienced bee-masters do not explain to us very fully why bees reject queens. When a patient consults a doctor he (the doctor) will first examine for the ailment, and then prescribe a remedy. Why not the same with introducing a queen, for when bees reject her it is an ailment, or there is a cause?

I will give my own way of introducing. Scientific men tell us that bees of the same colony know one another by the scent that the queen-bee imparts to them. Taking this as a starting-point, I first destroy this scent when I want to introduce a new queen. When my new queen arrives by mail I give her a little rest by laying the cage (face upward) in an empty hive or box. I now saturate a little sponge with sugar-water scented with a drop of peppermint, which I lay partly on the queen-cage so that the queen and escorts can sip at it, which they soon do, and their breath becomes scented with it.

Towards evening I go to the intended colony, and after treating the bees with smoke I remove their queen. I have a special hive-cover with a hole cut in, the size of the queen-cage, but about 1 inch longer. In this hole I lay the caged queen (face downward), and shove it forward so that the bees in the hive can not reach the candy plug.

I now cover that hole in the cover with about two thicknesses of burlap, which provides a little ventilation. Next I take a piece of lath and pour some peppermint extract on it, after which I stick it poker-fashion in the entrance of the hive. The next day when all becomes normal around the hive, I raise that burlap over the cage a little, and shove the queen-cage backward so that the bees can eat out the candy plugs and liberate the queen, and all is done.

Maybe our esteemed Dr. Miller will say that while the colony is thus strongly scented with peppermint the bees will not be able to distinguish robber-bees if such would make an attack. This may be so, but as yet I have not been troubled with it at that time, and as it is done later in the day most of the peppermint scent is fanned out of the hive by the next day.

A thing happened to me last summer which may be worth mentioning. I thought I had a case of robbing, and as I just then got my bee-paper, I saw where some one askt the question as to his bees fighting. Dr. Miller answered the question by stating it as paralysis, and it fitted my case also; and as the Doctor said that there was hardly a cure for it, it set my "thinker" going, and I thought of something to save a nice queen. As Webster describes "paralysis" as an involuntary motion of muscles, I concluded that if I could counteract this involuntary action it would be a case of cure or kill. At night I gave that colony smoke and whiskey, and two days later there was much less fighting at the entrance, but whether it was cured or killed I am unable to say. I think it was only the hardy ones that survived, and when I opened the hive I found that hardly enough bees were left to cover the brood. On another day I had a real case of robbing, which was done by a stronger colony next to it. When I noticed what was going on I smoked both the strong and the weak colonies. I then took the best comb with bees and all from the strong colony and gave it to the weaker ones. Judging that the new comers

were the strongest and fearing they might harm the queen, I scented again with peppermint, and closed up the hive, leaving the few field bees to take care of themselves. After night I also closed up the hive of the stronger colony, and gave both new stands, disfiguring the old stands as much as I could. The next morning I liberated the weaker colony first, and watcht if any of the added bees would find their old hive again, but they did not. Soon afterward I liberated the stronger ones also, and after an hour's confusion they went to work as before. But what surprised me most, was, I noticed no more fighting of the weaker colony, and by noon they were working in harmony, carrying out dead brood and cleaning house.

My bees are in chaff hives, and on the summer stands; they had a good flight on Dec. 23, and that weak colony seemed to have been enough to cast a swarm.

L. H. CREMERS,
Dec. 26, 1900.

Mr. L. H. Cremers and his Apiary, of Davison Co., South Dakota.

A Fair Italian—After "Black Beauty."

BY HENRY BIDWELL.

I am a yellow honey-bee of the feminine gender. My occupation is to secrete wax and build it into combs; to gather honey and pollen from the groves and fields with which to feed the maturing brood or to partly digest and give to the mother-bee for the rapid formation of eggs. The rule that governs the actions of my life is that whatever I find to do I delay not in doing. My mother is called a queen, but from her numerous progeny would more appropriately be styled a "mother-bee." My father is called a drone, but since he has no sac to gather honey in, no basket to carry bread in, and no stinger with which to defend the hive, he should be called the "gentleman-bee."

Mother and I, and 15 of my sister workers, came from Genoa, Italy, in a small box by mail. We had a quiet trip across the water, but were badly shaken up in transfer at New York City, then rolled across the country to our present home where we revel in the immense fields of alfalfa bloom, which we prefer to the fragrant groves and sweet-scented vineyards of our native land. This is the home of the industrious bee: here we enjoy the right to swarm when we wish to, as Nature intended we should. To swarm naturally is the greatest happiness that comes to us—God's way is better than man's way, at least, for our increase. In Italy we no sooner thought of swarming than our mother was removed and we were compelled to replace her from worker-larvæ which are confined in small cells and fed coarse food; so our step-mother came to us with her size reduced, her color darkened, the number of her ova diminished, and her vitality largely destroyed. Again, the German bee was imported and mixed with our race; this deteriorated our stock, left the brown stripes on our abdomens and inferior blood in our veins. But in America it was discovered that our race was variable, and by careful selection the brown stripes are being bred away.

It was a beautiful March day when we arrived at our present home. The bees, whose apiary we were to share, were returning laden with pollen from the maples. The box in which we were imported was placed in a strong colony of brown bees from which the mother-bee had been removed. Immediately our box was surrounded by the queenless bees that vainly tried to liberate us, and which in a measure consoled us by extending their tongues laden with liquid sweets thru the meshes of our prison doors. We gladly accepted the food offered us, but were even more glad the following day when released. Mother found many empty berths, recently vacated by baby bees, and at once began to deposit an egg in each cell, including a number of the drone-cells. In three weeks her brood began to hatch, and in four more she began to lay eggs in the queen-cells we had prepared for her.

We swarmed on the last day of May, just as the workers were going in to dinner after having mowed the alfalfa. We made the air quiver and hum as we flew in circles that grew larger until we were nearly all out, the yellow and brown bees mingling joyously; then the queen settled on a maple limb where we all clustered, bending the limb almost to the ground. We waited patiently for some one to hive us, but getting tired, sent out scouts in search of a suitable place to live. Soon one returned saying she had found an empty barrel; another saying she had found an open space between the siding and plastering of a house; another reported having found a hollow tree, and still another a small stone house which had never been occupied, for the padlock was sealed with rust. This seemed the most suitable, for our number was tens of thousands and we all wanted room to work. So away we flew, led by the scout, to the little stone building on a vacant lot near the center of town. We entered thru a crack over the door and immediately went to work. A few mud-wasps and spiders had been in possession of the house (which, by the way, was the calaboose) each year since it was built, but on account of there being no saloon in town it had remained vacant and we were left undisturbed.

In the course of a month we had built ten combs the size and shape of a bushel basket, suspended from the ceiling down into the center of the room. But on the night of July 4th the door was opened with difficulty, and a tramp was thrust in. He lay in a heap on the floor until towards morning when he got up and began to swagger and swear; striking out in the dark with clenched fist he knocked down our combs, scattering us all over the floor. Amid the yells of murder and fire we ran in every direction until we reached the sides of the room; then we climbed to the ceiling again

where we clustered. As soon as the light was sufficient we flew back and lit on a limb near our old home, which we found had been divided into ten parts—just the number of combs we had left in the hive. Each part had been placed in a separate hive and given one of the sealed queens which now were mother-bees. Looking about, we found an empty hive which we took possession of; and before winter we had it full of combs, honey, bee-bread and maturing brood. Sedgwick Co., Kan.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Transferring Crooked Brood-Combs.

I have six colonies of bees in the cellar. They are in frame hives without the frames, except three, but the comb is so crooked that I can not get them out or do anything with them. Will it pay to transfer them on frames of foundation?

IOWA.

ANSWER.—Wait till they swarm: have the swarm on the old stand, setting the mother colony beside it. A week later move the old hive to a new place, and 21 days after the time of swarming drum out all the bees and add them to the swarm. Then you will have the old hive free from all brood unless it be some drone-brood, and you can do what you like with the combs. The swarm having an extra force of bees ought to give you a lot of surplus honey, if there is any to be had.

Methods of Securing Increase.

1. I wish to get my increase the next season. My plan is this: In early swarming-time I think of taking the colony I wish to breed from, and take two frames with bees brood and queen, fill both up with empty frames with starters. Put the hive with the queen on the old stand; when the other has reared queen-cells within a couple of days of hatching, I divide as many more as I have spare queen-cells in the same way, placing the queens on the old stand and removing the queenless ones to a new place and give them a queen-cell. Will that plan work well? Will the bees destroy the queen-cells? Would I better give them the cell at once or wait a couple of days? If you think this plan will not work well, will you please give me a better one?

2. I have some extracted honey which fermented and then candied. Will it do to feed to bees in the spring if I liquefy it?

3. Since writing the above I have been reading an article by Mr. Doolittle in the American Bee Journal; he is good authority, and he advises against giving a queen after dividing, giving as a reason that it will bring on a crop of workers too late for the basswood and prepare the way for another swarm. His reasons seem good.

Please give me what you consider the best system of dividing. I wish as little increase as possible.

IOWA.

ANSWERS.—1. Instead of putting the queen with two combs on the old stand, and the queenless colony on a new stand, why not leave the queenless bees on the old stand and put the queen with her two combs on a new stand? The queenless bees will then be in a more flourishing condition to rear good queens, because strong in bees and getting a good harvest, whereas by the way you propose they would be weak in bees and gathering no honey. Then when it came time to use the queen-cells you could return the queen to the old stand. The bees will be likely to destroy the queen-cells unless conscious of their queenlessness. It would be a good plan for you to take the queen from the colonies you intend to use for nuclei two days before, then when you put them in a new place as nuclei they will stay better where they are put, and the queen-cells can be given to them at the same time. But remember that when you make a colony queenless not all the cells will be good.

Some of the last reared will be very poor. Better give each nucleus two, three, or four cells, and there will be a better chance that there will be at least one good one in the lot. You can also judge something by the looks of the cells, the large, well-pitted ones being preferred, altho sometimes an inconspicuous cell may contain a fine queen.

2. It will do very well. In spring, when bees are flying daily, it is safe to feed almost anything that bees will take. Possibly sweetened vinegar would do no harm.

3. Mr. Doolittle is a man of excellent judgment and a safe adviser. If your conditions are the same as his, you will do well to follow his example. If he lived where I do, I doubt that he would advise all to follow his example.

The Honey-Extractor and Foul Brood.

1. Does the extractor cause foul brood?

2. If so, in what way?

All the bee-keepers in this county (Davis), and a great number in Salt Lake County, will not use the extractor, claiming it does cause foul brood. UTAH.

ANSWER.—If there are no thistles growing on your place, there are two ways in which they may be introduced there—the seeds may be taken there, or the plants may. Without either plants or seeds there is no possibility of having the thistles. Foul brood in a colony is much like thistles on a farm. If there is no foul brood in a colony, it can only be introduced there by the introduction of a certain plant or its seed. The little plant is called *bacillus alvei*, and a spore is its seed. Please get that clearly in mind—there must be the bacillus or the spore, or there can be no foul brood. The bacilli or the spores may be found in the larvae, in the cells, or in the honey. Their presence in the honey is the thing most to be guarded against, for it is probable that in the great majority of cases it is thru the honey that the disease is carried.

Now for your question as to whether the extractor causes foul brood. If there is no foul brood in your apiary, how can an extractor cause it? The extractor can produce neither spore nor bacillus. If, however, there is foul brood in one of your colonies the case is a little different. You use the extractor to extract the honey of that colony, and that honey may be infected. You put a comb from the infected hive into a sound colony, and you have another case of foul brood. You put out the combs of the infected colony for the bees to clear up after they have been extracted, and there is a chance for every colony in the apiary to get the disease. If you feed some of the extracted honey for any purpose (and the chances are that you are more likely to feed extracted honey than comb), there is a fair chance that any colony thus fed will become diseased.

You will probably see now that the answer should be: There is no possibility that the extractor can produce foul brood where there is none; but if there is a diseased colony in the apiary it is quite possible that bad management in connection with the use of an extractor may greatly accelerate the spread of the disease.

Dead Bees Outside the Hive—Colony Destroyed by Moth.

1. Why is it that after a warm spell followed by cold, that a great number of bees are found dead outside of the hive?

2. Is it safe to use a hive after all the bees in it have been killed by the bee-moth? I caught three swarms myself, one of which was afterward destroyed by the moth. NEW YORK.

ANSWERS.—1. I should expect it to be the other way: after a cold spell when many bees have died, the advent of a warm spell allows the bees to carry out their dead.

2. The hive will not be injured in any way, and it will be perfectly safe to use it again. If you mean to ask whether it is safe to use the combs, the reply is that it will be all right to use them unless they are so badly destroyed that most of the septum or middle wall is gone.

I don't know whether you mean literally that the bee-moth killed your bees, but as it is a rather common belief among beginners that bee-moths may attack a good colony of bees and overcome it, it may be well to say a few words about it. No bee-moth ever came off first best in a hand-to-hand struggle with a worker-bee. If you watch closely, you may see a moth toward evening trying to enter a hive, and if a bee gets after it there is no attempt at flight. The

moth runs, and if the bees get hold of it it has no means to defend itself, let alone trying to kill the bee. The moth tries to get into the hive to lay eggs, and laying eggs is all the harm it does, altho that is harm enough. If bee-moths are plenty, you will probably find their eggs in or about the hives of your strongest colonies. When these eggs hatch out into larva, the larva or wax-worms make a business of eating the combs, and that's where the mischief comes in.

When these wax-worms are allowed full play, it will not be so very long a time in hot weather until the whole contents of the hive will be a mass of webs and cocoons, hardly anything in the semblance of a comb being left. But in the majority of cases it is no more right to say that the moths or the worms destroyed the colony than it is to say that maggots destroyed a horse that one finds filled with maggots, the horse having been shot some time before. The colony has in some way come to naught, and then the worms come in to make a finish of the combs, just as the maggots come in to make a finish of the horse.

Altho there may be eggs of the moth in the best colony you have, yet they do no more damage than the weed seeds that are found in your best cultivated ground. You keep the young weeds killed down before they get big enough to do any harm, and in the same way the bees keep the young worms rooted out before they get big enough to amount to anything. A strong colony will have no trouble in keeping the worms cleaned out, and even a weak colony will be all right if the bees are Italians.

Combs that have been out all winter so as to be frozen are safe until the weather becomes warm enough for fresh eggs to be laid in them. But if a colony dies in a hive, the combs will be ruined as soon as warm weather approaches. Put such combs under a strong colony of bees, and the bees will take care of them safely.

Sowing Cleome and Buckwheat.

When is the proper time to sow cleome seed?

When would be the time to sow buckwheat to have it bloom the first of July? WEST VIRGINIA.

ANSWER.—I don't know the answer to either of your questions, but I'll make a guess at them, and if I'm wrong some good friend will correct. Sow cleome as soon as frost is out and the ground fairly settled. To have buckwheat bloom the first of July, sow the first of May.

When to Put Bees Out of the Cellar.

When ought I to take my bees out of the cellar, in this section of the country? And should they be put in the same position and place as last year? ILLINOIS.

ANSWER.—You will not be far wrong to go by the blooming of the red or soft maple. When they come out in bloom, it is time for the bees to be out. Sometimes, however, the weather will be so cold and wet that it is better to delay a little if the bees are in good condition. On the other hand, if the bees are very uneasy, and are spotting their hives, it may be better to get them out the first favorable day. It is important to have a fine day for bringing out. After their long confinement they are anxious to get out of the hive, and if brought out on a bad day thousands of them will fly out, become chilled, and perish. After lying idle for months they can not be expected to fly with the greatest vigor, and a strong wind will beat them to the ground never to rise again. Bring them out on a still day, with the sun shining, and the thermometer at 50 degrees or more.

Having some years put my bees on the stands they occupied the preceding year, and other years having set them around promiscuously, I do not see that it makes any difference. Possibly in places where they are kept in the cellar a month or so, it might make a difference.

Our Wood Binder (or Holder) is made to take all the copies of the American Bee Journal for a year. It is sent by mail for 20 cents. Full directions accompany. The Bee Journals can be inserted as soon as they are received, and thus preserved for future reference. Upon receipt of \$1.00 for your Bee Journal subscription a full year in advance, we will mail you a Wood Binder free—if you will mention it.

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

THAT MAGNIFIED QUEEN PHOTOGRAPH.

I am inclined to get enthusiastic over that magnified photograph of queen and egg on the front of No. 9. Between "approximately correct" and "correct" is a long and important step. One of the great, grand things that we want of the twentieth century is to take away our approximations and give us some reals. For instance, let it take away our good novels, which are approximations, and a lot of our biographies, which are not so much as approximations, and give us some real views of other lives than our own. Well, here at last we have a real look at the queen on paper, can see the gloss on her back, and the fur on her shoulders, the exact shape of her foot, and the style of her "horns" (*a la l'uter*): can see that the true taper of her abdomen does not look like a wooden plug whittled out; can see the three little eyes on the top of her head, sticking up like crab's eyes, and ready (if they do utilize X rays) to locate just where the last egg on the other side of the comb was put.

SINGLE-BOARD COVERS, WIDE FRAMES, ETC.

I agree with Mr. Greiner that the single-board cover is not an improvement on the old telescope roof. Also I like the old wide frames for putting on sections. As to the old honey-board, I'll let some other fellow agree with him about that—doubtless "other fellow" will not be very hard to find. Page 89.

A LESSON ON THE LAMP-STOVE.

Friend Roe,
You ought to know
37's too low
For bees to go.

If you had known all that "with your heart," and had properly meditated on it last fall, perchance the treacherous lamp-stove would not have been invited to do its worst. Now sit at my feet while I shake my finger and tell you. Lamp-stoves are treacherous, even if you don't cover them up. Never should be left alone long. Liable to char their own wicks, and get up such a state of things internally as will set up an impromptu lamp-black factory—if not worse. Been there. Don't want anything worse. Interesting to see that the bees, even the aching for a temptation to fly at something were "controlled" by the smoke and kept in their hives. O smoke, thou art a daisy! Some angel (sister to the one that gave the moss-rose its moss) surely gave thee thy bee-controlling powers. Page 89.

ALTERNATION OF RAINFALL IN CALIFORNIA.

Ten years of California rainfall shows up as a regular alternation of first scant and then plentiful, except that 1899, which should have been plentiful, was instead the most scant of all—as if some cause, not connected with the law of alternation, had knocked it completely out. Page 90.

A CHILDER CHIDED A LITTLE.

Mr. Carlzen, page 91, chides Dr. Miller for not being explicit enough, and then proceeds to sin much more deeply and darkly himself. (No wonder we do just so after scolding.) The specific gravity of 20 is just that of quicksilver—and can not be his meaning. We would grasp at the theory that 20 is merely a slip for 20 hundredths, but that would be lighter than any fluid we have to do with. Perchance it's the arbitrary numbering of the scale on some little instrument he has; but how are we to know that unless he tells us?

SWARMING, ECCENTRICITIES.

The eccentricities related by Edward Knoll, page 92, seem to me to be instructive. Bees without a queen do not swarm, but a swarm left without a queen comes back soon. Here having gotten themselves partly on the end and partly on the roof of their home, they played that home hadn't any queen, and kept up the delusion for more than a week. Were not ready yet to give it up when the second swarm issued, but "saw the point" when the third swarm appeared. I surmise the old queen came out when she did because the bees had recently been worrying her—for them to kill her would be rather the normal course, I think.

PERHAPS THE FRENCHMAN WAS RIGHT.

Mr. Dadant, may it not be that that French manager was partly right? I mean about the non-advisability of working second-hand wood with power. Even here when a railroad wants old ties sawed up men do it by hand with big saws. Too many gravel-stones that have worked into cracks for buzz-saw work. Feeding a power saw allows too little time to "watch out;" and it can not be stooped when it strikes a stone. Page 100.

MAKING A COLONY SWARM.

Well done, Mr. Boyins! A practical way to make a colony swarm at will is one of the most urgent of our lesser wants, and you seem to have given us a good starter towards it. Booming colony—tall hive—queen in the attic—zinc to keep her there—then put her below just before the first princess emerges. There might be some failures, however. A phlegmatic colony might refuse to build cells below; and an irascible colony might kill the old queen when she appeared downstairs, and only save one princess. Page 101.

KEEPING EXTRACTED HONEY.

Dr. Mason was a little "off" on page 102 when he said it had never been tried how long extracted honey would keep. I've tried it a number of times when it didn't keep thru the first summer. How long the best, and most thoroughly ripened, select honey will keep is perhaps a little problematical yet. And his contribution 15 years in an open package, and good yet—is on the road toward finding out. As a general doctrine I should say that honey not sealed up depreciates *some* every summer it goes thru. Some innocent trader will get badly bitten by trying to hold too long a dozen barrels of honey—if he listens to our boys singing the imperishability of honey, as they are so fond of doing.

THE HATCH EXPERIMENT.

And, ye experimenting folks, don't forget the Hatch experiment when putting on supers this spring—filling all the mid brood-chamber with sealed brood, and having plenty of young larvae in the outside frames. For locations with only one harvest, and that not very long, I shouldn't wonder if this might prove valuable. Worth something to start the stirring in the outside sections, right over the young brood. Page 103.

BUMBLE-BEE DRONES WORKING.

Mr. Wallace, perhaps it is not very great merit in the bumble-bee drones that they work to the extent of getting their own food from the flowers. May be a simple case of "root hog or die"—no honey at home at all. It's true, however, that our hive-drones would promptly accept the "die" rather than the "root hog." Page 108.

UNCAPPING HONEY FOR EXTRACTING.

I am not an expert handler of the uncapping-knife—good ways from it, I fear—and therefore the photograph of an expert at his work has special value to me (and perhaps to all my numerous family.) I am talking now about the photographs of Mr. Aikin on pages 117 and 118. He does not lean his comb over to the right as much as I do. He cuts the first stroke on the near end of the comb. Had I been in his shoes, and commanded to begin on one end, I should probably have cut the first stroke on the far end—working the heel of the knife continually into fresh territory in preference to the point—except of course when the surface is so uneven that the point has to be used. While ago I used to take off a little strip pretty much all around the comb first thing; but I have pretty much abandoned that as a greenhorn's unprofitable fussing. Had I been in Mr. Aikin's shoes and told to uncup that comb just as I pleased, I should probably have set it on one corner, leaned it over strongly to the right, placed the middle of the blade under the bottom corner, and made the first stroke from that corner to the opposite or upper one. Then the rest of the territory I should have finished in a "pernicious" kind of way. Presumably, Mr. Aikin's way should be the better—but I should greatly enjoy hearing other brethren tell just how they would attack a comb—or, if they pleased, just how they would goat that particular comb which Mr. Aikin has in his hands.

Queenie Jeanette is the title of a pretty song in shee-music size, written by J. C. Wallenmeyer, a musical beet keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

INFLUENCE OF THE GOOD HOME.

The home is the greatest civilizer. A nation of good homes must be strong. Nothing will foster patriotism like the presence of innumerable homes where the beautiful is ever in evidence and where love is law. Anything that makes the home more beautiful, or anything that adds to its delights, not only makes good people—good fathers, mothers, children, good neighbors—but just as truly, good citizens. The man whose home is all in all to him, who longs for it when absent, and hies himself to it when business lets go her gripe, who is only away from it when stern duty calls, who rejoices in it from cellar to roof—such an one feels that he has great things to live for. He can accomplish great things, for he ever has a heart light with joy, he ever has wondrous incentive to work—thought of the loved ones that make that home so precious; his daily tasks are only pleasures. Such are the ministries of the true home. Such a man must be a patriot—he has that which is all priceless to defend.

The happiest homes, are where all work together to secure comfort—where all give thoughtful love and rejoice most in what brings joy and good fellowship to all. It is not the home of wealth, where money unearned, brings every luxury, and gratification in fullest measure comes without effort, that knows the truest happiness. Such homes breed selfishness, and selfishness and happiness never travel together. I would never covet wealth for my children or friends. I would covet the most generous, the noblest manhood. Such a state is not born of wealth. The man of wealth may hold onto generous purpose, unselfish regard, disinterested love, but his money is ever working to smother all these blessed instincts. Strong indeed is the man who can maintain his best integrity, and preserve ever alive within him the highest ideals of life, thought and purpose, if wealth has ever waited at his call and responded to his beck. Not the home of wealth, then, but the home where industry and frugality supply moderate needs, where daily thought and effort must minister to the daily wants, is where joy is sweetest and best, and such homes are what will surely give to a nation perpetuity.

May we not rejoice then that our nation is blest with such homes? Their influence is true and sweet. God bless every action and effort that fosters such homes. May God raise his hand against efforts that tend unduly and unrighteously to build up either the homes of squalor, or the homes of the over-wealthy.

Our American Bee Journal home circles are the average ones. In them all minister. All are ready to give the helping hand. All are alert to add a shaft to the store of comforts. Thoughtful love for other than self. All this is what makes glad some the home.

In our homes, we love to read. The good book and the helpful magazine are the pride and pleasure of the household. The reading aloud, and the good talks called forth, as "Wild Animals That I Have Known," takes us into the fascinating fields of nature, are too precious and valuable to be at all curtailed. How can we gain time for more? So very important is the answer, that we may well share no time or pains to make all about the house convenient. Labor-saving machines, no more than convenience of plan and arrangement, should receive fullest heed and attention. In all this as it is the workshop of the queen of the household—the loving wife who gives the sunlight to the home—a first place should be given to

THE KITCHEN.

The kitchen round of duties are every day, and many are oft repeated in each daytime. Steps that must be oft taken should be short and few. Is the kitchen the cheerful room, where sunlight and pure air ever keep company? Are the walls cheerful? and does an atmosphere of cheer and comfort make the kitchen a glad room?

Any pains to make the kitchen bright and attractive are well and worthily bestowed. Is the kitchen next to the dining-room, with double wall between, enclosing an ample cupboard, with convenient sliding or other doors that open both ways? Doors that slide either up or sidewise are most convenient.

Is the sink close beside this cupboard on the kitchen side? And has it an ample drain board, and both hot and cold water

that comes with a turn of a faucet? Suppose it does cost not a little, to secure all this. It is to help every day and oft-repeatedly, the dearest member of the household.

Is the range convenient to sink and table, and has it a hot water tank? And does a first-class quick-meal gasoline stove take its place in the hot weather? Is a neat wood-box close by the stove, and is it ever full of the best of fuel?

Is the arrangement of the cooking table to flour-bin and sugar-box, etc., so that all possible steps are avoided? Is there a long, narrow spice cupboard above the cooking table, with front door to open downward, that no steps shall be required to reach everything that is needed to make the food appetizing?

Is the pantry close at hand, and always stocked with all needed articles?

No husband can afford not to give all this most earnest heed. To save the time, the steps, the energy of the wife and mother, is his greatest privilege and his wisest and most blessed act. In building a house the most thought and study should be given to the kitchen, that it may be a model of neatness, beauty and convenience. If the house is already built, labor and money spent in remodeling this room so that steps may be saved, and care, worry and labor lessened, will be most wisely used.

THE BATHTUB.

That wonderful man, Booker T. Washington, in the intensely interesting and inspiring articles just completed in *The Outlook*, and which it is hoped will be published in book form, speaks of the bathtub, as a mighty civilizer. He is right. No house should be without the most convenient and best arranged bathing arrangements. Indeed, "*Cleanliness is next to Godliness.*" The bathtub—oft used—is the good angel of the home. We are wisest when we do everything to encourage to very frequent bathing. We must have the convenient bathroom, with hot water. Not to build this if it is wanting, is to stand in the very light of the home. The hot-water tank heated every time the stove is lighted, gives hot water at the kitchen sink and to the bathroom.

I would work my finger-nails short, if needs be, to have the best and most convenient kitchen and bathroom the county round. Have all our readers lived up to their opportunities in these directions? These should not be considered luxuries, but necessities—a thing not for the future, but for the now.

GRAHAM GEMS.

Nothing is more important in the home circle than good health. It is true that "what is one man's meat is another man's poison." White bread is often very unwholesome, and, I may add, unwholesome. To any who, like myself, have found this true, I would suggest as a substitute graham gems or bread. I feel that my health, if not my life, is due to this displacement. The following is the recipe for gems which I have found very appetizing and wholesome:

To two cups of graham flour and one of white, add two teaspoonsful of good baking-powder, and milk sufficient to make a thick batter. Salt to suit the taste. Add a half cup more or less of sugar. If some cream is added with the milk, no harm will be done. Bake quickly in hot buttered gem-irons.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and thus often leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one of the buttons! as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we have been furnishing to bee-keepers for a long time. It has a pin on the underside to fasten to the coat. Price, by mail, 6 cents each; two for 10 cents; or six for 25 cents. Send all orders to the office of the American Bee Journal.

The Chicago Convention Picture is a fine one. It is nearly 8x10 inches in size, mounted on heavy cardboard 10x12 inches. It is, we believe, the largest group of bee-keepers ever taken in one picture. It is sent, postpaid, for 75 cents; or we can send the American Bee Journal one year and the picture both for \$1.00. It would be a nice picture to frame. We have not counted them, but think here are nearly 200 bee-keepers shown.

honey-bee, but they copulate in the nest where they are hatched. I have seen more than half a dozen couples so engaged in a single nest at the same time.

The bumble-bee never builds its own nest, but it hunts up a nest that has been previously built by field-mice. I once found the house and hair of a mouse in the bottom of a nest occupied by the bumble-bee. It is not likely that the queen-bee killed the mouse, as it is probable that it had previously died of old age, or some accident. D. S. HEFFRON.

Cook Co., Ill.

Wintering Bees—Swarms Settling.

My bees are doing fine. I take common dry-goods boxes, having the top and bottom separate, set the hives on the bottoms of the boxes, then set the boxes over the hives, and fill in with chaff, leaving a space in front of the entrance. I have tried this plan for two years, and have not lost a colony. I get the boxes as near 30x20x20 inches as I can, and succeeded in getting two hardware dealers to save me 37 last fall, at 30 cents apiece.

I have seen a great deal in the Bee Journal in regard to bees settling after swarming. I have hunted bees ever since I was old enough, and have kept bees for several years, so I will give some of my experience.

I keep several hives up in the trees every year, and have never failed to catch bees in them. I have seen them work in and out of the hive for 42 days before they came to stay, but never knew them to take possession at once. Three different times I have seen them hang on the front of the hive from 3 to 50 yards. If the bees settle because the queen is tired, she must be *very* tired to hang within 4 inches to a foot of the entrance, so long. I have seen them in the woods hanging just below a small hole in a tree, and have gone back in a few days and found them at work.

Last spring a swarm issued from one of my colonies, and started off. I followed them to one of the neighbor's, where they settled on his barn, about 4 feet from the ground. My neighbor went back home with me to get a hive, and as we cross the railroad track we noticed several bees flying around. I found a queen with 17 bees. This was about 40 rods from the cluster. I bought a hive and a queen-cage, put the queen in the cage, and set the hive at one side of the track, and ask my neighbor to watch the cluster, and if they entered the hive he might take them home and keep them. The second day at noon they went into the hive. Next day I went over and liberated the queen for him. They stored 24 pounds of surplus honey, and cast one swarm. He says they were over on the barn waiting for that queen in the hive to rest. I think that sometimes they have to settle in order to rest the queen, but I have caught the queen in my hand while flying in the air, after more than three-fourths of the bees had clustered. H. GILBERT.

Jasper Co., Iowa, Feb. 4.

Bee-Keeping Experiences.

I paid \$3.50 for the first colony of bees I ever bought, and they were in a large-made of oak. Some time afterward I moved a little further west, and worked for a man who kept about 25 colonies. We got the fever to go still further west, so we sold what we could and traded the balance. We sold what honey we had at 18 cents per pound, and could have sold more if we had had it.

During the civil war, while on the field of battle one day, in an old house that was full of bullet-holes, I found a colony of bees, which I gave to the good woman who had done some sewing for me. I have some relics from the old battle-field where the battle of Monmouth was fought.

After the war I struck out for the West, and landed in Madison, Wis., about the middle of May, 1864. That part of the country was then a wilderness, with very few houses scattered about. I soon found a bee-keeper with two colonies of bees in oak box-hives, and offered him \$10 for one. He did not want to sell, but that was all the bees there were in the village. Soon after that I heard of a man 10 miles out in the country who kept bees, so I went to see him, and offered

him \$10 for a colony, but he did not want to sell either. I finally found a swarm hanging on a willow bough, and thus began bee-keeping.

The winter of 1914-15 I had 17 colonies—16 in straw-hives, and one in a box-bive. On the last day of the year (1914) the snow drifted day and night, and it was so cold that a great many people had their ears and noses frozen. My bees were near the house with oil-cloth covering over them. A few days after the storm the sun shone brightly, and I saw no signs of the bees flying about, so I knocked on the hives, but received no answer. To my sorrow I found that they were all dead. So I had plenty of honey and wax to sell to cobblers and tailors the next spring. I then bought about a quart of bees and a hybrid queen for \$2.50 from an old friend, and started in again.

I was 50 years old last Christmas, and I go four miles to and from my apiary every day in the summer-time, and occasionally in the winter to find out the temperature of the beehive. I have half of the bees in the cellar, and the best outdoors. I had to feed them, but I have about 30 colonies that I think will come thru the winter all right, as the weather has been favorable.

The largest swarm of bees I ever saw was working in and out of a tree on Lone Mountain, Calif., 26 years ago.

God bless Dr. Miller; may he live long to be a help to bee-keepers, and if he ever comes my way I should like to have him come to see me.

I have a son in the bee-business. We feel that we must have the American Bee Journal as long as we keep bees. D. D. DANHER.

Dane Co., Wis.

Prospects Bright for the Coming Season.

I have 30 colonies of bees in winter-quarters. This is a clear day, the sun is shining brightly, and the best outdoors. I had to feed them, but I have about 30 colonies that I think will come thru the winter all right, as the weather has been favorable.

The past season was a poor one for honey in this locality; dandelions bloomed until November.

I am glad that the "Old Reliable" did not go up in smoke at the time of the big fire in the building in which it was located. I have been a reader of the American Bee Journal for 25 years, and as long as I keep bees I expect to take it. IKA B. NYE.

Posey Co., Ind., Feb. 17.

Bee-Keeping in Indian Territory.

I want to ask some questions, as I am alone here, and get all my information thru the American Bee Journal, the "ABC of Bee-Culture," and experience. The most of the "bee-brethren" are up North, and very little is said about bees in this part of the country.

I notice that one of our expert bee-keepers has been on a trip to Sebastian Co., Ark. I wish he would kindly give thru the American Bee Journal, his impressions on bees and the prospects for making a success with an apiary in that country.

We have wild-flowers, cotton-plant, persimmons, black locust, ash, willow, wild fruits, and berries in great abundance, but can one make a success of the bee-business with these plants?

This has been a very warm and open winter, and there has not been more than 45 hours at any one time in which the bees were not flying. I put 50 colonies into winter-quarters, and I believe every one of them are alive, altho they must be short of stores, for I understand that they consume a great deal more honey in a warm winter than in a cold one.

Last fall, when taking off supers, I found that only about one-half of the sections were filled. I let the bees clean the partially filled ones, and stored them away in the supers. In coming over them now I find quite a lot broken and partially destroyed—or you might say ragged. What would be the best thing to do with them? Shall I cut out all the comb and put in new starters, or will the bees fill out the comb? I had very bad luck last summer in introducing Italian queens, and

those I succeeded in introducing did not do nearly as well as my blacks.

From one large early swarm of blacks I took 252 pounds of comb honey, which I think was doing very well for a new colony. They still had eight full frames for winter stores. From some of the others I got only one super full, and from many of them I got nothing.

I had the worst case of robbing that I ever heard of last season, but I will know better another time.

Quite awhile ago I wrote an account of my great loss by fire, of my entire stock of goods and store-houses, twice inside of 15 months. I did not feel able to continue taking the Bee Journal, but after reading about the man that wrote such an unkind letter in regard to stopping his paper, and your very generous answer, I will take his place and continue my subscription, so you will not lose anything, but make a friend of me.

R. N. CRAFTON.

Cherokee Nation, Ind. Terr., Feb. 14.

Hard Winter on Bees.

We have had a hard winter on bees. Mine did not have a flight for two months until March 3d, when it was warm enough for them to fly. I found 8 colonies out of 100 dead. They are wintering on the summer stands.

W. W. TAYLOR.

Ottawa Co., Ohio, March 6.

Fears Losses in Wintering.

There are going to be some bee-losses I fear. It looks as if new colonies in unprotected thin hives were pretty much all dead already.

E. E. HENRY.

Lucas Co., Ohio, March 6.

CONVENTION NOTICE.

Chicago—The next regular meeting of the Chicago Bee-Keepers' Association will be held Thursday, April 4th, at the Briggs House, Chicago, from 1 p.m. until those present get tired and quit, which is usually 7:30 p.m. A feature of the meetings lately has been the opportunity to dine at 5:30 in a company. All are urged to be present and help us all have a good, old-fashioned time. HERMAN F. MOORE, Sec.

Utah—The Utah Bee-Keepers' Association will hold its regular spring meeting April 5th at 10 o'clock a.m., in the City and County Building at Salt Lake City. All are cordially invited. We expect to get out a treatise or pamphlet, the object of which will be to give the best and quickest method to discover, cure, and prevent disease among the bees, and the best way to protect them from their enemies. It will also contain other matter for the benefit of the industry, including our State law. We will be pleased to receive communications from any of our bee-keepers upon any subject along the lines indicated. Address, Pres. E. S. LUTZ, Salt Lake City, Utah, or J. B. FAGG, Sec., East Mill Creek, Utah.

A Little Wonder Incubator.—The larger incubators are not necessarily the only good ones, and we are glad to tell you that the 50-cent Bantam Incubator made by our advertiser, the Buckeye Incubator Co., of Springfield, Ohio, which is one of the most satisfactory batches of its class on the market. The Buckeye people put into this little machine the same care and thorax construction found in their larger sizes. It has made some wonderful records even in the hands of beginners. Moreover, the price at which it is sold is so low no one who has even a small flock of hens need do without an incubator. It is sold on 30 days' free trial, and money will be refunded if the incubator is not entirely satisfied. Lately several improvements have been added to the machine, one of them being a metal lamp instead of a glass lamp. While the glass lamp produces results in every way satisfactory, still the metal lamp is safer and more durable. A novel feature of their larger machines is a separate regulating apparatus for each separate incubator, which not only insures more even temperature when the machine is being run at its full capacity, but admits the use of each chamber independently of the others if so desired. More details pointing to the 50-cent are fully shown and described in their catalog. We trust those of our readers who are leaning toward the purchase of an incubator will write the Buckeye people for their catalog, which is a plain, straightforward statement of the busi-

ness-end of the proposition, and we believe will most favorably impress any one with the desirability of these incubators. In writing please mention having seen their advertisement in the American Bee Journal.

Tennessee Queens!

Fine lot of Choice Test Queens reared last season, daughters of select imported and select golden queens, reared 3½ miles apart, and mated to select drones, \$1.50 each; untested warranted queens, from same breeders, either strain, 75c each. No bees owned nearer than 2½ miles. None imported within 3, and but few within 5 miles. 2 years' experience. Discount on large orders. Contracts with dealers a specialty. JOHN M. DAVIS, 6A2d Spring Hill, Tenn. Please mention Bee Journal when writing.

A New Radish.—The John A. Salzer Seed Co., La Crosse, Wis., are the introducers of this year of a magnificent new radish—a radish fit for use every day of the year—because they have named it "Salzer's Everyday Radish." They say it is a radish worthy to grace the table of every king, monarch, president or citizen of the United States and the world. There is nothing quite so rich, so luscious and fine as the tender and juicy, and sweet, and crisp, as Salzer's Everyday Radish. It is a large red radish, shading into white, peerless in quality and beauty, and is sure to give satisfaction. Not only are the Salzers introducers of new radishes, but they have a long list of vegetables that can not be excelled anywhere. Their catalog is worth \$1.00 to any and every tender and gardener, and is mailed to you upon receipt of but 5 cents postage. When writing please mention the American Bee Journal.

PAN AMERICAN EXPOSITION.

Nothing since the World's Fair, at Chicago, in 1893, has elicited the widespread interest that is manifest, all over the world, in the Pan-American Exposition, which is to be held in Buffalo, from May 1 to Nov. 1, 1901.

The purpose of the Exposition is to illustrate the progress of the countries of the Western Hemisphere during a century of wonderful achievements, and to bring together into closer relationship the people composing the many States, Territories and Countries of the three Americas. Acting under proper authority, the President of the United States has invited all the Republics and Colonies of the American Hemisphere to join in commemorating the close of the Nineteenth and beginning of the Twentieth Century, by holding this International Exposition on the Niagara Frontier.

For this important event, the Nickel Plate Road has issued an attractive, descriptive folder—pamphlet, elaborately illustrating the Pan-American Exposition, the buildings and grounds.

The Nickel Plate Road is the short line between Chicago and Buffalo, and affords competent train service from Chicago to Buffalo, New York City, Boston, and all points East, with trains of modern equipment, on which no extra fares are charged; also dining-car service of the highest order. It affords meals in its dining-cars on the individual club plan, ranging in price from 35 cents to \$1.00.

Call on any ticket agent for Pan-American folder of the Nickel Plate Road, or address John Y. Calahan, General Agent, 111 Adams St., Chicago.

Parties desiring hotel or rooming accommodations at Buffalo or Niagara Falls, during any period of the Pan-American Exposition, are invited to apply by letter or otherwise to F. J. Moore, General Agent, 291 Main St., Buffalo, N. Y. No. 14-21A3t

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, March 8.—Fancy white comb sells readily at 16 cents, but all other grades are weak at the following range of prices: No. 1, white, 14½-15c; fancy amber, 12½-13c; light amber, 10½-11c; buckwheat, fancy, 10c; off grades, 8½-9c. Extracted white ranges from 7½-8c; buckwheat, 6½-7c; Southern dark, 5½-6c; amber grades, 4½-5½c. Beeswax in demand at 30 cents. R. A. BURNETT & Co.

KANSAS CITY, Feb. 19.—Fancy white comb, 16½-16c; amber, 12½-13c; dark, 10c. Extracted, light, 9c; amber, 7½-8½c. Demand fair; receipts light. Beeswax, 22½-23c.

W. R. CROMWELL PRODUCE CO., Successors to C. C. Clemens & Co.

CINCINNATI, March 9.—The demand for comb honey is nearly over, the stock of it also well cleaned up. Fancy white brings yet 16c. Extracted good fair demand; dark sells for 8½c; better grades bring 6½-7½c; fancy white clover at 7½-8½c. C. H. W. WEBER.

ALBANY, N. Y., March 12.—Honey market is dull with light demand and very little stock, either comb or extracted. White comb, 15½-16c; mixt, 12½-14c; fair demand; 12c; mixt, 10½-11c. Extracted, white, 7½-8c; mixt, 6½-7c; buckwheat, 5½-6c. H. R. WRIGHT.

BUFFALO, Mar. 7.—Fancy, 15½-16c; No. 1, 14½-15c; No. 2, 11½-12c; No. 3, etc., 8½-10c. Extracted, 8½-9c. Beeswax, 25½-26c.

All grades of honey selling fairly well, and looks as if all lots would clean up.

BATTERSON & CO.

BOSTON, March 11.—Fancy No. 1 white in cartons, 17c; No. 1, 16c; No. 2, 15½-16c, with a fairly good fair demand. About equally no call for dark honey this year. Extracted, white, 8½-9½c; light amber, 7½-8c. Beeswax, 27c.

BLAKE, SCOTT & LEE.

NEW YORK, Feb. 19.—Comb honey is being well cleaned up, and our market for the demand has lessened to quite an extent, on account, we presume, of the high prices which have been ruling. Fancy white still brings 15½-16c in a small way; No. 1, 14½-15c; No. 2, 12½-13c; buckwheat, 10c. Extracted rather dull and not much doing. California white honey, 7½-8c a pound; light amber, 7c; Southern, from 6½ to 7c per gallon; buckwheat, 5½-6c. Beeswax, steady at 26c. HILDRETH & SEGELKE.

DETROIT, Mar. 7.—Fancy white comb, 15½-16c; No. 1, 14½-15c; dark and amber, 10½-12c. Extracted, white, 8½-9c; light amber and dark, 5½-6c. Beeswax, 27½-28c. M. H. HUNT & SON.

SAN FRANCISCO, Feb. 6.—White comb 13½-14c; amber, 11½-12½c; dark, 8½-9c. Extracted, white, 7½-8c; light amber, 6½-7½c; amber, 5½-6½c. Beeswax, 26½-27c.

Considering the light output of honey last spring from California apiaries, present offerings are of tolerably liberal volume and are mostly of amber grades. The market is slow at the quotations. It is reported on good authority that adulterated and imitation honey is being dealt out in considerable quantity, which accounts in a great measure for the very limited business doing in the pure article.

HONEY MARKET.—We may have a customer within a short distance of you who wants your honey or beeswax. We are in close touch with all the markets; therefore, if you are regarding your crop, stating quantity, quality, and lowest cash price. References—Either Bank here for any business man in this city.

\$200 Red=Clover Queen

Offer No. 35.

On September 1st last we announced that we finally had a red-clover queen fully equal to the one we had years ago. The colony of this queen has given one of the most remarkable showings on red clover of any bees we have ever had. The queen in question is an imported one, and therefore of the genuine pure leather-colored Italian stock. We sent out daughters from her all the season. But we did not discover her value until the clover season, second growth, came on, and then her colony so out-distanced all the other 450 that she attracted attention at once.

It must be understood that these queens are not golden yellow, neither are their bees of the five-banded stock. They are simply leather-colored Italians whose mother came direct from Italy.

Since the notice appeared regarding this queen we have hardly been able to supply all of the queens that were wanted from this stock. Many daughters of this queen we sent out before we knew her value, and it now transpires that some of the finest bees in the land are from queens we sent out early. We are now looking orders for the coming season, and make the following offer, but no queens will be furnished except those that subscribe for Gleanings, and only one with each year's subscription. All arrearages must be paid to the end of this year. Gleanings for 1901 and one untested red-clover queen, \$2.00; Gleanings one year and a tested red-clover queen, \$4.00; a select tested red-clover queen and Gleanings one year for \$6.00. We will begin mailing these queens in June, 1901. Orders are already entered, and the same will be filled in rotation. Do not neglect to improve this opportunity and get some choice stock, and send your order early so you may get the queen correspondingly early in the season. We are using every precaution to winter this queen safely, but reserve the right in case of her loss this winter to substitute from other select tested stock of this strain which we are holding in reserve, or to give the subscriber the benefit of any of our other clubbing offers if desired.

THE A. I. ROOT CO., Medina, Ohio.

The Bee-Keeper's Guide;

Or, Manual of the Apianry.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary; it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book is 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with name and address) and you will receive Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

Long-Tongued Bees

ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers (with \$4.00).

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation—"first come, first served"—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO

144 & 146 Erie St., CHICAGO, ILL.

28 cents Cash
paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 28 cents a pound—CASH—for best yellow.

upon its receipt, or 30 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO.

Best White Alfalfa or Basswood Extracted Honey

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

A sample of either, 6y mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are box.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

41st YEAR.

CHICAGO, ILL., MARCH 28, 1901.

No. 13.

* Editorial Comments. *

Prof. Cook's Review of the "ABC."—When publishing Prof. Cook's first article of the review of the "ABC of Bee-Culture," we should have stated that his criticisms referred to the edition of 1890-1900, and not to the latest, or 1901 edition. As the criticisms read, one would naturally infer that they relate to the new edition, and not to the previous one. With perhaps two exceptions, all the matter which Prof. Cook criticised in his first article has either been stricken out or materially modified in statement. Only about half of the edition of 1890 could be revised, owing to the limited time at the disposal of the revisers, but when the latest edition (the one for 1901) was under consideration, that matter which had not been changed was either rewritten or revised. So, as it happened, Prof. Cook is calling attention to certain errors and other points that needed modification, but which are not in the book *now offered for sale*. This is well, as only a very few, comparatively, have a copy of the 1901 edition, the great majority having former editions, which contain the criticised matter.

Prof. Cook quotes E. R. Root as saying that "digestion is the separation of the nutrient part of the food from the non-nutrient, and the conversion of the nutrient into a liquid fit to mingle with the blood." This is not Mr. Root's statement, but a direct quotation from Mr. Thos. Wm. Cowan, and, with all deference to Prof. Cook, Mr. Root writes us that he should not know whether to accept Mr. Cowan's or Prof. Cook's definition even yet. When doctors disagree, who shall decide?

Regarding the statement of the poor quality of honey from apple-blossoms, so much proof was furnished Mr. Root to the effect that such honey was of the very finest quality in color, body, and flavor, that the 1901 edition contains a statement praising that kind of honey in the highest terms.

Regarding the other points referred to in Prof. Cook's review of the "ABC of Bee-Culture," the 1901 edition either does not contain the statements which are called in question, or else said statements are modified to conform to the knowledge of the present time.

Mr. Root has sent Prof. Cook a new book bearing the date of 1901, in which he will see that his suggestions and corrections have been generally adopted; for, be it said, a copy of the 1899 edition was sent to Prof. Cook, requesting him to point out its errors or its misleading statements, which he did.

Bee-Keeping for Women.—When the statement is made that bee-keeping is just the thing for invalids and women, a quiet smile is likely to be seen on the face of the bee-keeper who works hard at his business from "dawn to dewy eve," and who lies down at night more worn out than the average farmer. He knows that bee-keeping takes work—hard work—and a lot of it. He knows that he is no invalid, and yet the business requires all the strength he has. As a matter of fact, when bee-keeping is spoken of as a business into which invalids and women can enter and rapidly make a fortune, the realm of non-sense is entered.

And yet, taken in the right sense, it is not so far out of the way to say that bee-keeping is just the thing for an invalid woman. Not perhaps for every one, but for every one who has taste and adaptability in that direction. Indeed, there are not wanting those who test that with poor health and too little strength for almost any physical

exertion, when the time comes for the merry hum of the bees in the spring, they can go to work at their pets, using up their strength to its limit every day, but every day finding that strength on the increase.

There are two reasons for this. One is that they are kept out in the open air, that of itself being enough to make a vast difference in most cases. The other reason is the intense interest that bee-keeping begets. Many a bee-keeper will readily recall the time when he had not more than five or six colonies, and when at the close of a hard day's work in some other direction he has worked an hour at his bees, and when everything was done that he could find any reasonable excuse for doing, he would reluctantly stop, with regret that there was nothing more to do. If the occupation had been almost anything else, he would have found himself so tired that he would have been glad to have shortened up the task.

The woman who enters bee-keeping with no knowledge of the business, and with no love for it, but only with the thought that she may make a fortune at it, will be badly worsted in the outcome; but if she has some taste in that direction, and goes at the matter reasonably and intelligently, she may find a delightful recreation, and with gradual increase of colonies she may add to her pin money a sum not to be despised.

The attention needed by the bees can be given at a convenient time so as not to interfere with other duties, supposing that the number of colonies is not large, and when the number becomes sufficiently large, help at other duties can be obtained. In any case, it will not be hard to get help from "the lords of creation" in any part of the work that requires much physical strength.

Mrs. Axtell's article on this subject in this week's number will be read with interest, particularly by the women of the bee-keeper's family.

Immune to Bee-Poison.—One of the German bee-papers reports that "Dr. J. Langer investigated 164 bee-keepers, and found 11 of them immune to bee-poison from the start; 126 became immune after a time; and 27 remained as sensitive as ever. Some lost their immunity, and sometimes suddenly thru sickness." So says a *Stray Straw in Gleanings in Bee-Culture*.

Editor Root says that he has never yet met a person who is immune to bee-poison from the start—that is, one on whom there would be no swelling at the first sting. Of course, there are persons who never can keep bees, owing to the fearful effect of the poison caused from stinging. The result of the investigation made by Dr. Langer shows quite conclusively that after a time the great majority become almost completely immune to bee-poison.

When we first began to keep bees we suffered greatly from the effect of the bee-poison. We remember very distinctly being stung above the eye, on one occasion, and the next morning we could scarcely see anything with that eye. After keeping bees a few years, and being stung more or less, we noticed that the pain became less after stinging, and that there was scarcely any swelling at all. Now, when being stung, we scarcely realize it half an hour afterward, unless it is a very severe case.

"Practical Lessons for Beginners in Bee-Culture," by Rev. J. D. Gehring, of Douglas Co., Kans., are begun in this number. There will be several of the lessons, forming a series, which we trust will be read with interest and profit, especially by those who are inexperienced, and have so many kinks to learn in connection with bees and bee-keeping.

It may be true that "anybody can keep bees," but it is certainly true that anybody can keep them profitably or successfully without making a careful study of the business. While everything can not be told in the bee-books or papers, yet there is very much that can

and must be learned by reading. We all learn by picking up an idea here and a thought there. Then in the aggregate there is quite a good deal of practical value gathered together. It is much like the bee when getting the nectar which it transforms into honey—a drop here and a drop there, of sweetened liquid, then to the hive where it is “boiled down” into the honey that is so delicious. We must, after reading, “boil it down,” by thought and meditation, to the consistency that shall make it usable and valuable. Thus will our reading, of whatever kind, prove to be helpful and profitable.

Contributed Articles.

(Edition of 1899-1900.)

No. 2.—A Review of “A B C of Bee-Culture.”

BY PROF. A. J. COOK.

(Continued from page 149.)

PAGE 147—It is stated that there are 53 different varieties of goldenrod. This is an incorrect use of the word variety. The goldenrods are species. The same as our bee—*Apis mellifera*. A variety or subspecies is one of the less marked divisions of the species. The Italian bee is a variety or subspecies of *Apis mellifera*. In the figure on the same page, the three plants each represents a species.

PAGE 172—I am surprised at Mr. Root's style on this page. “Tarnal nuisance” and “pawed out” might do in Gleanings in Bee-Culture, possibly, but some would quite object to them in a book like “A B C of Bee-Culture.” Still, this is a matter of taste, and I may be hypercritical.

PAGE 173—The typographical errors in this book are few, but there was evidently faulty proof-reading in referring to the first figure on this page. The letters should be reversed.

PAGE 174—The figures of the book are usually clear and admirable, but the second one on this page I think a failure. I think the first one on the previous page gives a much clearer idea. This figure appears to me like a small cube inside a larger one. I should consider it a right-angled figure.

PAGE 177—A strange error occurs here, for which I fear my own poor chirography may be to blame. Mr. Root speaks of the coccids as scab insects. This certainly should be scale insects. I have a dim recollection that in one of my own articles written some years ago, the typesetter made my scale a scab. I fear that this is what misled Mr. Root. The statement is also made that these honey-dew-secreting insects—plant and scale lice—propagate in the topmost limbs of the trees. I doubt if this is correct, in fact I know it isn't. They attack the tree anywhere where they may happen to locate. All female scale insects, and many plant-lice, are wingless, and so are conveyed from tree to tree by bird or other insect. If they are left on the topmost branches by these carriers, they would very likely locate there. They are only carried when very young, and they are at this time exceedingly minute, and if left to their own means of locomotion, make progress slowly. We see, then, that accident alone determines what part of a tree they will occupy.

PAGE 179—I am quoted on this page to the effect that much aphid honey-dew is deliciously wholesome, and the honey from it superior. Mr. Root follows this with the assertion that “the ordinary stuff that we have in Ohio, and that which I have seen in other localities, is usually of a dark color and rank flavor, to me very sickening and unpleasant, and as Prof. Cook says, it should be sold to bakers and others desiring an inferior or strong-flavored honey.” The error Mr. Root makes here is easily explained. I have no doubt but that the honey from Aphides is almost always of pleasing flavor, and so always makes good honey. I have never seen a case in which this was not true. While in the Yosemite last summer, away upon one of the highest peaks (Cloud Rest) 10,000 feet above the level of the sea, we ran across plant-lice on the pine trees. There were no bees in the region, and the honey-dew was present in great drops so that it was very easy to test it. All of our party pronounced it excellent. Perhaps I should say this was before they were told where it came from. This aphid honey-dew is common every year in nearly all sections of the country. Yet it is so

unobjectionable that almost no one knows it. The bees take to it, and I doubt if they will often leave this even for the nectar of flowers. I have certainly known them to work on the honey-dew of the larch right at the time of the white clover bloom. Many of the bees were gathering from the clover, others were taking from the honey-dew. The mixture all sold readily as clover honey, and I am sure no wrong was done any one. The bark-louse, or coccid honey-dew on the other hand, is not so common, and is only present in certain years when the scale are very numerous. Another fortunate peculiarity is that it is distasteful to the bees, and they gather it only in times of drouth when the flowers are not secreting. Indeed, the scale insects of the East prosper most in a succession of dry seasons, just at the time when the flowers do not furnish nectar. The honey from this source is dark and rank, and well deserves the opprobrium Mr. Root has put upon it. I think our bee-keepers should all understand this distinction, and should become acquainted with the aphid honey-dew. It may be flavored. If so, it has not come under my observation.

PAGE 185—Two mistakes of faulty proof-reading are evident on this page. One of the beggar-ticks—*Bidens frondosa*, is referred to as *Burr marigold*. This should be *Burr marigold*. Likewise, *Leonurus cardiaca* should be motherwort instead of motherwort.

PAGE 193—Our author refers to the thorax of the bee as the shoulders. He shows the abdomen detach, and states that it is detach from the shoulders. This use of the word is not warranted by any good usage that I know of, and as thorax is a perfectly good word, I see no need of coining a new one.

PAGE 204—The letter “O” is omitted as marking that division of the work. Uniformity would be better observed if the “O” were supplied.

PAGE 213—A case of misspelling is made very prominent on this page. I think it is always spelt jasmine or jasmín. I have grave doubts as to the honey from this or any other plant being poisonous. It would be so easy to make the mistake. We know that honey makes some people seriously ill whenever eaten. That it might occasionally make a person sick who usually was proof against the ill effects is easily to be believed. I can understand how Xenophon might have made a mistake. A lot of hungry soldiers eating freely of honey would in almost any case give employment to the doctor. We know that falsehood once on the race-course spans the world while truth is harnessing her steeds. We can easily see how this idea of poisonous honey, once started, would run rapidly. If jasmine or mountain laurel do furnish poisonous honey, I can not understand why the evil effects are not more frequently experienced. I have received this so-called poisonous honey several times, and have eaten it without any ill effects. If I found any really poisonous honey, I should look to find if the arsenites had not been used at the time when the bees gathered the honey. I have known of cases where the larva of bees have been seriously poisoned by receiving honey poisoned with Paris-green which had been applied at time of bloom in the apple-orchard.

PAGE 214—In describing the way that bees get pollen, Mr. Root credits the tongue with an important part of the work. I have never noticed that the bee used its tongue to get the pollen. The antennae cleaner on the front leg gathers the pollen, not from the tongue but from the antenna. I hope others will observe and see whether Mr. Root is right in the explanation. My own observations would the rather teach that the compound hairs which clothe the body so generally, and the legs of the bees, are the instruments used to gather the pollen. I doubt if the tongue has anything to do with it.

PAGE 222—Our author does well in using the development theory to account for the color of blossoms and birds. It is perhaps modest to say, “I can not positively affirm.” I think, however, that no scientist to-day has any use for the interrogation-point in using the evolution hypothesis to account for the color in flower, fruit or bird. To question it shows that the writer or speaker is not conversant with the latest in scientific research. We are glad that Mr. Root has never been one to be afraid of truth.

PAGE 227—Is it wise to say that ten-day queens may be just as good as any? If I am right, experience, no less than theory, would argue against such queens. The bees give us a good lesson in this matter. When things are normal they start the queen from the egg. I think the wise breeder will always do the same.

PAGE 230—It is very interesting if Mr. Root's views regarding the presence of eggs or larvæ stimulating the

young queens to lay be correct. If it be true, I have no doubt it is owing to the fact that the bees were stimulated so that they fed the queen differently. Is it not more probable that it was simply a coincidence? I think a good many experiments should be tried before we reach this conclusion.

Page 232—That the thread which evinces that mating has taken place is absorbed into the body of the queen, I think very improbable indeed. It is of a kind of tissue that would be slowly absorbed, and want of contact would make absorption very slow. That it could dry up and disappear is easy to believe.

Page 250—I am not at all sure that bees do not communicate. A study of their brain would make this seem possible. That they are one-idea insects seems also to me not proven, as the judge would say. The very case Mr. Root gave, I think would warrant this conclusion. When bees are not gathering, how quickly honey some distance from an apiary attracts multitudes of bees if exposed. I think Sir John Lubbock would give a decided "no" to this idea, that bees do not communicate. If any man living has a right to an opinion regarding the intelligence of ants and bees, it is he.

Page 255—Here again Mr. Root advises the use of the lantern. I have tried the night-working with bees several times when necessity compelled it, and I should be slow to recommend it, especially to a novice.

Page 261—Mr. Root's commendation of California in view of the prolonged harvest is very timely. The white sage of the valleys precedes the black sage of the canyons, and, as he so well says, "the bees first commence working in the valleys and then gradually fly higher up as the blossoms climb the mountain sides, giving a much longer season than we have in regions not mountainous." There is another fact that greatly extends the period of bloom in California—many flowers, like the white sage, are in long racemes which bloom centrifugally, that is, the outside flowers bloom much earlier than the inside flowers, or the lower flowers blossom earlier than the upper. This, of course, greatly prolongs the period of bloom, and consequently, the honey season.

Page 276—What warrant is there for stating that formic acid is a vegetable acid secreted from the honey and pollen? I think there is none. I believe that it is equally untrue that the poison is more pungent when the bees are working. The formic acid is a secretion of the insect, and in no sense a vegetable secretion. If the poison is more irritating at one time than another, it is because there is more of it. When bees are idle, all their functions will be less active and so less poison would be secreted. Yet I have my doubts in this matter. I have never known bees to sting worse, or the wound to be more painful, than in the autumn when the harvest was all over.

Page 277—I am surprised that our author teaches that stinging does not kill the bee. Who has not known cases where thousands of bees have died from stinging? In the case of the cow killed by being stung, which I described in the bee-papers some months ago, so many of the bees lost their lives that the apiary was sadly depleted. I have proved by direct experiment, that losing the sting means to lose the life. Death, however, may not immediately follow the wound.

(To be continued.)

Adaptability of Bee-Keeping to Women.

BY MRS. L. C. ANTELL.

I AM surprised that some women do not take up bee-keeping as a business, for I am sure they would find it profitable, conducive to health, and a pleasure, if followed perseveringly.

As bees never ought to be handled except in warm weather, in taking care of them there is no need of exposure in unsuitable weather, as is often necessary in other outdoor work, especially in caring for poultry. I have often seen women out in a pouring rain gathering up little chickens, and have done it a great many times myself.

Keeping bees is light work, requiring but little heavy lifting, except when putting the bees into the cellar for winter, and that is not really necessary, as they can be made warm and dry and left on the summer stands. Simply remove all extra combs and surplus from the hives, and fill the empty space with dry chaff, first covering the combs the bees occupy with thick cotton-cloth, to prevent the chaff from falling down among the bees.

If bees are gentle it is a real pleasure to me to see them flying around and hear their happy hum among the flowers—they are company just as all life is company. A few neatly painted hives set in the front or side yard add to the beauty of the premises, making a home look attractive. I would not have the bees very near to the walks, as some people are afraid of them.

Some of our most successful apiarists are women. Most men bee-keepers have women helpers. Indeed, much of the work to be done with the bees seems just adapted to women, as they are more likely to look after the little things than the men. Where a home is heavily mortgaged, if the wife or grown-up daughter would engage in bee-keeping, she could do much toward lifting the heavy burden from the shoulders of the husband and father. Even if there are no debts to pay it is nice for a woman to have some money which she feels she has earned herself, as there are so many ways in which she can use it—for benevolences and the like—and there is real joy in giving what one earns one's self. Then, it is quite a help to have plenty of honey to use; it doesn't require any preparing, or cooking, and if unexpected company comes a section of nice honey or a dish of candied honey helps to fill up the table, and most people enjoy eating it.

I think one great reason why more women do not take up bee-keeping is because they are afraid of the stings. But if Italian bees are kept, and handled gently, working with them only when the weather is warm and sunshiny, always giving them a puff or two of smoke at the entrance before opening the hive, having the face protected with a bee-veil and the wrists tightly wrapt, a woman will soon become so used to them that she will have no more fear of the bees than of a sitting hen. Bees resent quick movements so it is well to move slowly and easily when working with them. It might be well for two beginners to work together, one to use the smoker while the other works, but care must be taken not to use too much smoke. The odor from a crushed bee seems to anger them, but a little smoke will subdue them.

When a woman makes up her mind to begin bee-keeping she must begin right. Buy good hives, and good colonies of pure, gentle Italian bees—not the very yellow ones, as I have had the very yellow Italians that were worse to handle than any blacks or hybrids we ever had. The queens of such colonies should be destroyed, and ought never to be sold to beginners. Then the next thing she should have is a good text-book on bees—don't buy an old one because it is cheap, but get one that is up with the times. Follow the book very closely the first few years, and pay little attention to what a neighbor advises unless you know him to be a practical apiarist. It is better to have few colonies at first, and I am not sure but that it is just as well to have five as one, as it seems hardly worth while to spend the time reading up for only one colony when one can just as well look after three or five.

Many women will say they have no time to spend in caring for bees, and yet they spend much time working in the garden, and with flowers, or poultry, and none of these things pay as well for the time expended as do the bees. Better have a few colonies of bees, and a little less of something else—perhaps fewer ruffles and tucks on the children's clothes, or make less pies and cakes.

In order to make bee-keeping easy and successful we must do everything at the right time, and have things in the right place. Bees will not put up with slipshod ways. We must follow their instincts more or less, and help them in following them out to the best advantage.

If weak women would have the care of bees all to themselves, and be removed from all other work and care, very many of them would find their health. I know this from experience. Working with the bees has done me more good than hundreds of dollars spent for medicine could have done.

There is something very fascinating about bee-keeping, and when once a woman gets interested she forgets her aches and ailments, especially if she has enough colonies to look after to keep her busy. When swarming begins, and being short of help, she will see it that the swarms are cared for if she is only half alive, and the work will become so exciting and exhilarating that before she is aware of it she will be on the fair road to recovery. She has been working out-of-doors, breathing the fresh air, been somewhat sunstuck, heard the birds sing, and forgotten her own troubles; and bodily ailments have taken unto themselves wings and flown away. Warren Co., Ill.

Large Brood-Chambers For Queen-Rearing.

BY G. M. DOOLITTLE.

A CORRESPONDENT writes thus: "Will you please tell us something about rearing queens in large brood-chambers, in the American Bee Journal? I use a large one-story hive holding 15 frames, running parallel with the entrance, so I can not very well use the plan requiring an upper story, as given in your book. How would you proceed to rear queens in such a hive as the one spoken of above?"

The hive spoken of by the correspondent is very similar to the one which I used when the plan of rearing queens in a hive having a laying queen in the same, first came to my vision. Some years before I had made four hives on the "long-ideal" plan, which was brought to public notice a score or more of years ago by D. L. Adair, of Kentucky. These hives were used a few years for extracted honey, but laid aside, as I found it paid better to work my apiary more wholly for comb honey.

Soon after this, D. A. Jones, of Canada, came out with a new plan for working for comb honey, in which he placed the queen and six to eight combs of brood in the center of a long hive and filled out the ends with sections, claiming that in this way large quantities of section honey could be produced without much swarming; and as these long-ideal hives would be just the thing to try the experiment with, it would cost me very little to see what there was in the plan. So I changed the combs and bees from my regular hives back into these hives again, put in two queen-excluding division-boards, so as to shut the queen on five or six combs in the middle of the hive, according to his plan, when the first thing which came to my notice in opening the hives a week later was sealed queen-cells wherever there was any unsealed brood left which the queen did not now have access to. These I carefully removed, till there came a time when work crowded so that the removing of these cells was neglected till they hatched, went out of the hive, were fertilized and commenced to lay, so that I had two laying queens in some of these hives. Had it not been for this experiment in producing honey on the Jones plan, in all probability "Scientific Queen-Rearing" would never have been written, for right here was where I got my first ideas on the subject which finally developed into the matter found in the book.

In carrying out the Jones plan wide frames of sections were put next the apartment containing the queen, and, every ten days or so, some of the combs that had been with the queen, and were now full of eggs and brood, were taken out and placed beyond the wide frames of sections toward the ends of the hive, and empty combs placed with the queen to take the place of those removed. In this way the queen was given all the room she required for laying, the bees kept from swarming, and the bees coaxed to work in the sections to the greatest advantage. And it was on these frames of brood, placed beyond these wide frames of sections, where these queens were reared as spoken of above.

It will be noticed that there were wide frames of section between the combs where these cells were reared and the queen-excluding division-board which kept the young queen in her place, and these wide frames had separators on them which tended to keep the young queens from going to the perforated zinc and quarreling thru it with the old queen. As the plan of securing honey in this way was a failure in my hands, these hives were cast aside again, and the upper-story plan was adopted as given in my book. But I have found from long experience, that, where ever there is unsealed brood on which the bees cluster, but from which the queen is excluded by means of perforated zinc, enameled cloth with a hole or two in it, or a division-board with a crack in the same, the bees will generally build queen-cells on these combs, and if it is so that the young queen hatching from these cells can not "touch noses" with the old queen, and if there is a place of exit from the part of the hive in which this queen hatches, she will generally, in due time, become fertile, when a honey-flow is on, and go to laying, the same as she would if there were no other queen in the hive.

Hence, to rear queens in such a hive as our correspondents uses, all we have to do is to fix the same so that two or three combs of brood can be put in one end of the hive, and between these combs of brood and the apartment having the laying queen, put two queen-excluding division-boards, these latter being half an inch apart, so that the queens can not touch each other. From past experience, my way of fixing such hives would be to keep the laying queen in the rear end, on as many combs as I desired her to occupy, placing next to her apartment a queen-excluding division-board. I would now place two empty combs next to this

division-board, and immediately in front of these but in another queen-excluder. I would now fill out the remaining space between the last excluder and the front end of the hive, or entrance, with combs of brood and honey, and rear queen-cells there, and have them fertilized from the same, as I gave in my book.

Now, while I have told what I would do when using such a hive as the correspondent says he is using, yet I do not feel like closing this article without saying that, in a locality like central New York, such a hive is not the one for the practical bee-keeper to use if he wishes to produce the most honey with the least capital and labor.

Onondaga Co., N. Y.

No. 1.—Practical Lessons for Beginners in Bee-Culture.

BY REV. J. D. GEHRING.

I WAS working in my apiary one beautiful May morning transferring brood-frames from one hive to another. It was what bee-keepers would call a typical bee-day. I had hived four swarms that morning, and the bees were fairly crazy in their eager rush and hum, gathering in the rich nectar which the blooming white clover was yielding in great abundance that season. I was stooping over an open hive, in the act of taking up a frame of brood, when I heard my name spoken, and some one saying, "I would just like to know what you are doing with that hive of bees?"

Straightening myself up hastily, I saw directly in front of the hive at which I was working, and standing within a few feet of the entrance of the same, a ruddy-faced, cheery-looking man, whom I knew as Reuben Bond, a farmer living about four miles out of town. At the same moment I also saw that Mr. Bond had hitched his team of beautiful young horses to a post of my yard-fence, not more than 25 feet from the first row of the bee-hives. Taking in the significance of the situation at the first quick glance, I for the moment ignored his friendly salutation, and said:

"You are in danger there, Mr. Bond—better come away at once. Your horses are in danger, too, where they are. Suppose you take them around into my back yard, while I close these open hives and get ready to talk to you where it is more quiet and safe than it is here at present."

But, tho I had lost no time in being decently polite, my admonition came too late for Mr. Bond. My last words were scarcely uttered when I saw him slap his right hand to his face, and, uttering some incoherent exclamation, start on a stooping run toward the house, and before I could do or say anything, darted down the open stairway of the cellar, and was out of sight in a twinkling.

I closed my two open hives and followed him, directing my son, who just then came around the corner of the house, to take care of Mr. Bond's team. I found the runaway just inside the door of the cellar, puffing and blowing, and rubbing the end of his nose. Noticing his action, I knew where to look for the instrument of torture. Drawing him toward the open door, where I could see, I gently lifted the sting out by placing my thumb-nail under the poison-sac, instead of grabbing hold of it with thumb and finger, as bee-sting doctors usually do, and thus squeezing into the wound all the formic acid contained in the little sac attach to the sting.

"Never rub a bee-sting," I said to Mr. Bond, "until after you, or some one else, has performed the operation I have just shown you how to do properly. It's a lucky thing the little fury didn't hit you in the eye. We can apply almost any kind of a remedy to the nose, but not to the eye."

"Aint it queer, tho, how quick those pesky bees left me when I got in here," remarkt Mr. Bond, as he gently rubbed the end of his nose. "What do you do for bee-stings?" he askt, as we ascended the cellar-stairs.

"Usually I pay no attention to them," I replied; "because usually I am stung when I am too busy to run away from my work and doctor bee-stings. I seldom get stings in the face, however, because I wear a bee-veil whenever I do work among the bees that is liable to put them on the defensive. They always fight in defense of their home and property, Mr. Bond, and seldom for any other reason. And there is no telling when bees will not sting when they are being disturbed, and they suspect that the disturber intends some sort of mischief to them. The principal reason, however, why I wear a bee-veil is, because they always aim for the eyes when they have a chance and the disposition to sting. And, as I always need my eyes, even more than my

hands, and nose, Mr. Bond, when I am busy with a hive of bees, I wear a veil to protect them. When a man tells me—even if he is an old bee-keeper—that he never wears a veil in his apiary work, and that he never gets stung, I am disappointed to think that he is talking thru his last year's hat.

"Now come with me to my honey-house and I will see what I can do for your nose, Mr. Bond. I use alcohol for bad stings—red-hot ones, like the one you got on your nose—when I use anything at all. I will let you try it.

"Here," I said, after we had entered the room in the honey-house that I called my workshop. "I always keep a bottle of alcohol for emergencies. A small sponge saturated with some of it and applied to your nose for about ten minutes will relieve the pain and reduce the swelling. I think the alcohol neutralizes the formic acid in the sting-wound."

"Now, please tell me," said Mr. Bond, after several minutes silence, "why I got stung the minute I stepped in front of that hive you were working at, and you, with your hands and your nose right down among the bees, wasn't touched."

"That's easily explained, Mr. Bond," I replied. "I account for it in this way: My bees know me. They are accustomed to my presence and to my manipulations. You, on the other hand, are a stranger. They know you as such by sight and smell. Then, to make bad worse, you plant your perspiring person directly in front of their only door, and so near that they can't help but regard you as an intruder, with evil intention toward them. There are always a number of bees on guard at the entrance of their hive, and these guards are very vigilant. No doubt they saw you at once, and one of them took aim at your face and struck your nose. A hot sting like that is never an accidental one, I can assure you. It's a good rule never to stand in front of a hive of bees, or even to walk past near the entrance unless you can't possibly do otherwise."

"I believe in that rule implicitly since my late experience," remarked Mr. Bond. "But, will you now tell me why those bees that followed me to the cellar left me as soon as I got inside the door?"

"They left you because bees never go into a dark room if they can help it—except, perhaps, to steal honey—and, because they were satisfied as soon as you were out of sight when you got there. And here let me mention the fact for your benefit, that a person who is being stung and followed by a lot of angry bees can do nothing that so promptly and completely defeats them as to run into a room. A dark room, of course, is best, but any room will do better than to run about outside vainly fighting them. They give up as soon as they find themselves prisoners—always and everywhere."

"That's a very interesting fact to know," remarked Mr. Bond: "but I don't quite understand what you mean by saying, 'my bees know me.' You don't mean by that that bees in general have sense, do you?"

"Yes, Mr. Bond, I certainly believe that bees have sense. But my belief is surely not orthodox, for, everybody—even the vast majority of bee-keepers—give bees credit for a high degree of instinct, and nothing more. But can you tell me what instinct really is? Can anybody tell me what the distinction is between instinct and intuition? By intuition we know things as by instinct. That is, intuition is knowledge which is not acquired thru the reasoning process. No one can prove that bees can not and do not reason. I can mention several things that bees do that they couldn't and wouldn't do by instinct alone. Here, for instance, is a sample of their work"—taking a pound section of white-clover honey from an open crate near me and holding it up before him as I spoke. "Examine it and see if it isn't perfect in every detail. See how white and even the comb is, and how beautifully it is fastened to the wood of the section all around. When they put that honey into those cells it was not honey, but nectar, or sweet water, very little thicker than water. They converted it into honey, thick as the best sugar syrup, by evaporating it. And how, do you suppose, do they know that evaporation is necessary? and how do they do it? They know by instinct, I suppose, and they seem to know, too, that fanning the open cells of sweet water will thicken it to its proper consistency."

"The bees seem to have sense enough, too, to understand that this fanning work is best done during the night, when all the nectar gathered for the day is stored in the combs, when the hive needs extra ventilation on account of the heat caused by the whole colony being at home, and because it saves precious time. It's the bees that do the work of gathering the nectar that must also do the evaporating work. Drones will not do it, because it's work, I

presume; and the baby bees in the hive can't do it before they have learned to fly.

"Now, Mr. Bond," I continued, "look at the surface of this comb. You see it is perfectly smooth and regular, and almost snow white. I have 1,600 like this stored in my honey-room just beyond the partition, all filled and sealed like this, since the first of this month, by 16 colonies. You see, they not only know how to work, but how to do the best kind of work. They make no mistakes, and they never seem to forget anything. One of the most curious things about this comb work is, that there is an air-space between the honey and the wax with which the surface of the comb is covered, or sealed. How they manage to produce this air-space, and how they know it to be necessary, are bee-secrets which have never been whispered into inquisitive ears. But bee-keepers do know that, but for this air-space, that beautiful white surface of the comb would be an impossibility, because without it the honey would come in contact with the wax, soon softening it, causing it to break up and let the honey ooze out. You can see how important this little item becomes when you realize the fact that with this air-space omitted by the bees, shipping comb honey to the markets would be out of the question. We would be limited to extracted or liquid honey."

Before I could proceed to explain further, Mr. Bond suddenly jumped to his feet and looked anxiously out of the window that afforded a view of the apiary and the street beyond. I knew what the movement meant, and could afford to smile as I said:

"You are anxious about your horses, Mr. Bond. Well, you needn't be. My boy put them into the stable and fed them soon after the fracas. If you will go with me to the house, we will now have some dinner, and I will show you my wife and children. Then, if you care for another dose of bee-talk, I shall be glad to have you spend the afternoon in the shop with me. I have a lot of sections to put together and prepare with comb foundation, and I can talk while I work."

(To be continued.)

REV. J. D. GEHRING.

The subject of this sketch was born Dec. 15, 1837, at Buchberg, situated at the foot of an isolated haystack-shaped mountain bearing the same name. It is presumed that the mountain existed before the town, hence it is also presumable that the town was named for the mountain.

From the top of this mountain the snow-clad Alps could be seen. The famed "Rhinefall" at Schaffhausen, Switzerland, is within hearing distance of Buchberg.

His father, at the age of 60, emigrated to the United States in 1848, with wife and eleven children, and bought a small farm in Fulton County, Ohio.

Mr. Gehring enlisted as a private in Co. C, 27th Wis. Vol. Infantry, served three years, and was mustered out a 1st lieutenant, and as a cripple for life. Disability was caused, mainly, by a sharp-shooter's "minnie ball," which passed thru the back of his neck, fracturing the vertebra, and resulting in partial paralysis of the left side. Other serious results developed as time made history and old age.

He began keeping bees in Parkville, Mo., in 1844, started with two colonies, both presents from friends who didn't know what to do with them, and were anxious to get them out of the way for fear of getting stung. Transferring these two colonies to "movable-frame hives," and handling over 300 pounds of white-clover honey, in pound sections, the first season, persuaded his then easily-impressible mind to believe that he had now ceased to be a keeper of bees, and had become a bee-keeper instead. Mr. Gehring keeps his front door latch-string always hanging outside for visiting "friends" of the ancient craft.

Thru a somewhat remarkable combination of circumstances he and Miss Anna J. Doty were brought together in 1866, and have continued the happy union as husband and wife into this the 20th century. Five children four

daughters and a son—are in evidence to propagate the parental union of German and Scotch-Irish blood.

It may not be amiss to say for Mrs. G. that *she loves bees*—in the abstract sense—but bees never learned to love her—not, however, because she is not a lovable woman, but, rather, because her husband's bees never seemed disposed to let her get intimately acquainted with their way of doing things when they were out of humor. It was not owing to any fault in her character; nor could the fault have been owing to her Scotch-Irish descent, that Mrs. Gehring's earnest effort to become her husband's "help-mate" in bee-keeping was a failure from the start. It remains a puzzle in Mr. G.'s mind to this day why bees—well-trained and usually well-behaved like his were—should behave so badly toward a sweet, mild-dispositioned and loving little woman as ever blest the life of a bee-keeper. But these bees did treat her badly—on a certain special occasion—and the resulting coolness between her and the whole apiarian tribe will end only with life.

Referring to the Falls of the Rhine, in Switzerland, Mr. Gehring writes us as follows:

The Rhine is one of the most interesting rivers in the world. Its source is among the Alpine glaciers of Switzerland, and its waters enter the sea thru the lowlands of Holland. On its banks is every variety of scenery, towering mountains, wild and picturesque rocks,

Falls of the Rhine at Schaffhausen, Switzerland.

dense forests and fertile plains. It flows between flourishing villages and populous cities, castles and ruins with which a thousand legends are connected. Along its course for many centuries great historical events have been taking place; the victories and defeats of the Romans, the heroic deeds of the age of chivalry, the coronation of kings, the meetings of ecclesiastical councils, and the wars of modern times. We can not wonder that such a river is regarded with little less than reverence, and that great numbers of tourists come from all parts of the world to look upon it.

The upper Rhine is especially remarkable for beautiful scenery. The Falls of the Rhine near Schaffhausen form one of the finest cascades in Europe. The breadth of the river above the falls is 126 yards, and the height of the unbroken fall is about 60 feet. If the rapids above and below are taken into consideration, the total fall is nearly 100 feet. Not far above the falls is a bridge known as the "Rhinefall Brücke" (Bridge of the Rhinefall). High above the river on a wooden rock stands the Schloss Laufen (castle of the rapids). From a garden of this picturesquely situated edifice the best view of the falls may be obtained, one gallery projecting over the roaring, seething cataract.

In the year 1845, when eight years of age, my Aunt Ann, a sister of my mother, took me on a visit to my grandparents, who resided about nine miles northeast from the falls, and about 18 miles from my home on the banks of the Rhine below the falls. On the way we passed thru Schaffhausen, and stood together, hand-in-hand (I being afraid to stand alone) upon the bank of the river viewing the awe-inspiring scene. The spot where we stood was a little way below the cataract, not far from the old mill seen upon the left bank in the picture. The railroad bridge above the falls was not there then. There was no railroad in all Switzerland before 1850. JOHN D. GEHRING.

The Chicago Convention Picture is a fine one. It is nearly 8x10 inches in size, mounted on heavy cardboard 10x12 inches. It is, we believe, the largest group of beekeepers ever taken in one picture. It is sent, postpaid, for 75 cents; or we can send the American Bee Journal one year and the picture—both for \$1.00. It would be a nice picture to frame. We have not counted them, but think here are nearly 200 beekeepers shown.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Drones and Swarming.

1. If I destroy all the drones from a colony that wants to swarm, will this prevent swarming?
2. When a swarm leaves a hive, and I have the Alley queen and drone trap on, are you sure the swarm will return to the hive?

SUBSCRIBER.

ANSWERS.—1. No; but it is thought there is less likelihood of swarming if drones and drone-brood are kept down. But it can by no means be counted on as a sure prevention of swarming.

2. If you have only one colony, you may count to a dead certainty that in the case you mention the swarm will return to the hive. In any case you may be sure that the swarm will not go off, and under ordinary circumstances that it will go back to the hive from which it issued. But if it should happen that a little while before another swarm had issued and returned to its hive, the bees still making a loud call at the entrance of the hive, your returning swarm might return to this latter hive instead of returning to its own.

Tall vs. Square Sections, Etc.

1. I began bee-keeping last year and now have 36 colonies. My troubles are caused by the great variety of bee-supplies. I have 60 supers meant for 4 $\frac{1}{2}$ x 4 $\frac{1}{2}$ bee-way sections. Now I want tall sections with no bee-way. I think of buying 60 supers designated "L." These take 4x5 sections. Now, can I alter the old supers so they will carry 4x5 sections? I'm afraid robber-bees will get in.
2. Will filling all cracks with white lead injure bees in any way?

3. I think of using full sheets of light brood foundation in all frames when hiving swarms, these sheets to be wired. Is this a good plan?

4. Do you prefer tall sections with no bee-way to the old-style square ones with bee-way?

5. Are the combs less liable to be built together? and do the bees enter them as readily do they sit across the frames?

COLORADO.

ANSWERS.—1. There are so many different surplus arrangements that take 4 $\frac{1}{2}$ sections that it is impossible to tell how much change would be required; but by the exercise of a little ingenuity almost any of them could be changed to take 4x5 sections.

2. It will do no harm.

3. An excellent plan.

4. It is largely a question of one's market. Some prefer one and some the other.

5. You will probably find no difference.

Bees Diseased and Dying—Closed-End Frames.

1. I took 12 strong colonies of bees on shares last spring. One or two swarmed and almost all stored a little surplus. When I prepared them for winter—that is, took off the supers—they had plenty of honey and appeared to be strong, and along about January 1st, I examined and found all dead but three. On examining the combs of the dead ones I found fully $\frac{1}{2}$ of the cells with cap brood, with a small puncture in the cap, and an offensive smell, not like a glue-pot. I took five back to the owner last summer that were too weak to defend themselves, and I didn't want any robbing. The owner (a beekeeper of 20 years' experience, so he says) claimed it was caused by moths. The bees I have here haven't any moths in the hives; besides, I haven't any trouble with the moth, anyway.

2. If it is foul or pickled brood, why do they die in winter without any brood, and be stronger in bees than some of my weak ones?

3. What course should I take to prevent it from spread-

ing to my own bees? I fear they got some of their honey. The diseased colonies have been destroyed by fire and water, and every caution preserved all summer, or while I have been suspicious.

4. I went to a sale of a bee-keeper who made hives to sell of his own invention, and bought several for almost nothing. Knowing nothing about the hive, I would like to be enlightened. I enclose a pen outline of it. There being no space at the ends of the hive, will the bees winter as well as on Langstroth frames? It is what I would call a closed-end frame.

INDIANA.

ANSWERS.—1. I don't know what the trouble is, but it can not be charged to the moth.

2. Whatever disease of the brood, or whether any, there seems to have been some wintering trouble that would produce such loss.

3. Keep everything as snug and clean as you can, taking special precaution to prevent all robbing of infected or suspected colonies by allowing no cracks or too large entrances to invite robber-bees. Be sure that none of the suspected colonies are weak. If they are, unite them. There will be no real loss in this, even if nothing is wrong with them. Carefully study all you can find that will inform as to the brood diseases of bees, including what has been said in back numbers of this journal and Dr. Howard's brochure on foul brood. A thorough knowledge of the whole subject will enable you to judge more intelligently what is to be done than can any one at a distance.

4. It would seem from the pen sketch that the end-bars of your frames form the end-walls of the hive, after the fashion of the Quinby-Hetherington standing-frame hive. Not a large number of bee-keepers use this hive, but a few use it in very large numbers. The end-bars are sufficient for the end-walls of the hive, but some use an outside case to set down over the whole as additional protection in spring.

Basswood for Brood-Frames—White Clover—Honey in Candles.

1. Is basswood all right for brood-frames, or will they be short-lived?
2. Is there more than one variety of white clover?
3. Is there much honey used in candles?

WISCONSIN.

ANSWERS.—1. Basswood is not too short-lived for brood-frames, but entirely too lively. You probably know that it is unusually bad to swell and shrink, and it twists out of shape altogether too much for anything that needs to be as exact and permanent as a brood-frame.

2. There is the common white, and the white Dutch. The latter is said to be a large kind, and sown on rich soil it grows quite large. But so will the common, and I feel sure the two are one and the same thing.

3. Probably not. It would be very much better for the public if some of the glucose in candles were replaced by honey.

Bees Dying—What is the Cause?

Of 76 colonies that were in fine condition about Dec. 1st, there remain alive at present 30 colonies, and I expect some or all to die soon if nothing can be done for them. They all had plenty of honey so that was not the cause, or at least the quantity. The bees could not fly one day for nine weeks. Of those that are dead, part of the bees are on top of the frames in a mass, and part in some lower corner; and all, alive or dead, have the inner part of those hives, including frames and bees, perfectly wet and soiled; also it smells very strong. All are on the summer stands. Some were in single-wall hives, some in chaff hives, some had chaff cushions over the frames, and some had none, but all are affected alike. There was hardly any honey for the bees to gather last fall, and they worked freely on half-rotten and bruised apples in various orchards; but some received their entire supply of winter food by feeding granulated sugar as late as Sept. 20th.

May it have been caused by doses of poison not sufficiently strong to kill them while gathering it? It is very probable that they received some. What shall I do for them?

WEST VIRGINIA.

ANSWER.—This is one of the times when it is painful to say I don't know, and yet I am obliged to say it. Working on rotten apples in orchards could hardly do so much mischief, unless there were cider-mills from which they

obtained large supplies. It will hardly do to lay the trouble to the general stores, for some had their entire supply of granulated sugar. The guess that there was poison in the case seems a reasonable one, but if it were poison would it not have killed the bees sooner? The thought comes that the entrances may have been closed so tight that there was something like suffocation in the case, but a man with 78 colonies has in all probability had too much experience to make that mistake. In any case the trouble was no doubt aggravated by the confinement of 9 weeks.

It is nearly certain that in your latitude bees are now flying, and there will be some good luck by cleaning up all the hives and getting out the dead bees. If the trouble continues after the bees have had a good flight, try at least a few by taking away their stores and giving them sugar syrup. It is to be hoped that a good flight will do much good.

Sugar-Candy for Winter Feeding of Bees.

In the "A B C of Bee-Culture" (1891 edition, I think), there are directions for making hard candy for feeding bees, by boiling sugar with a little water. I believe Mr. E. T. Abbott has also frequently recommended such candy. I wish you would tell me thru the American Bee Journal if you have ever tried such candy, and with what results. I considered the above authority so good that I recommended it in a couple of instances before trying it myself. I also risked a few colonies on such feed and just happened to discover in the nick of time that it doesn't seem to do for this "locality." In short, one colony was dead—clustered right up against the candy—and one was about half dead, that is, a large portion were just able to hang to the combs—too far gone to crawl around. The other colonies all had a little honey yet and were all right. I hastened to give them combs containing some honey. The candy had been on only a week or two, and the colonies were in good condition when it was given. They are pacted with leaves on the summer stands, and there has been no cold weather to speak of—a very mild winter here. They gnaw thru the candy and it falls on the bottom-boards about as granulated honey looks when the bees have such in their combs to use. I am sure the candy is not burned, in fact it looks just as Mr. Root says it should—"dry and hard as slabs of marble"—and about as valuable, according to my experience. What say you were wrong?

IOWA.

ANSWER—I have never had occasion to feed candy, but would have said with no little confidence that you would have no trouble whatever. I must confess that your experience staggers me, and I don't know enough to account for it. I suppose that tons of candy have been fed, and I do not remember to have read a single report like yours heretofore. It looks somewhat as if there had been so much stirring that it was stirred down to sugar, but that could hardly be the case if it stuck together as candy. If any of the good friends can throw any light on the case, it will be a great favor. Has any one else had a similar experience?

Convention Proceedings.

Report of the Michigan State Convention.

BY WM. G. VOORHIES.

The Michigan State Bee-Keepers' Association held its annual meeting at Traverse City, Mich., Dec. 26 and 27, 1900. The meeting was called to order by the president, and Mr. A. L. Root offered prayer.

The president made a few remarks referring to present needs, and the purposes and educational work of the Association.

GETTING BEES TO WORK IN THE SITS.

A. S. Dobson—How can we get bees to work in the supers?

Mrs. George Jackson—Smoke them up into the sections when the brood-combs are filled with brood, and they will work there if you put on some unsealed sections.

W. Z. Hutchinson—Put on unsealed sections.

George Hilton—When using deep frames, and the bees do not enter the sections readily, take out the side frames that are filled with honey, and extract it; then return the empty frames, but put them in the center of the brood-chamber. When the bees will not work in the supers it is sometimes because there is too much honey in the brood-chamber, and this choked condition is often caused by honey being carried over from the previous season. We have to put supers on early in northern Michigan.

Mr. Hutchinson—To get the bees to work in the supers, half or partly filled sections are sometimes used. Get the bees to clean out these unfinished sections the fall before, and in the spring they can be used. Sometimes the outside frames in the brood-chamber are filled with honey. These can be uncap and placed in the center of the brood-chamber, when the bees will carry this honey up into the sections.

Mr. Beecham—I can not always get the bees to work in sections or starters.

Mr. Hutchinson—I use drawn combs to get them started. Wm. J. C. Davis—I have had no trouble with bees not working in the supers.

Mrs. Jackson—I have had no trouble with bees loafing. I tier up the supers with partly filled sections.

POLLEN IN THE SECTIONS—CROSS BEES.

Mr. Beecham—I produce extracted honey altogether. I have had trouble with the Heddon hive, as I have to use a queen-excluder. When I produced combhoney and had to use a queen-excluder the bees put pollen in the sections, and the queen sometimes got thru the excluder and laid eggs in the sections.

Mr. Hutchinson—I have no trouble with pollen in the sections, and would suggest that Mr. Beecham put a comb in the brood-chamber from which the honey has been extracted, and this comb would take the extra pollen. I should think that being bothered with pollen in the sections in this way was a good deal a matter of locality.

Mrs. Menold—When the frames are filled with honey I take out one of them and put a new one in its place.

Mrs. Menold—What shall I do with cross bees?
Mr. Hutchinson—Change your queens.

WINTERING BEES—PUTTING ON SUPERS.

Mrs. Menold—I do not winter my bees in the cellar. I put a dry-goods box over the hive and pack hay between the box and the hive.

Mr. Beecham—I have had trouble with bees storing honey on frosty nights. I would like to ask Mrs. Jackson if she winters her bees in the cellar.

Mrs. Jackson—Yes. I do not put them out until the willows bloom, and I put on sections in apple-bloom.

Mr. Beecham—I think that bees should be protected on cold nights in the spring. For the past two years I have wintered mine in the cellar, and think that when they are so wintered they will dwindle in the spring.

Mr. Coveyou—I think that the supers should be double-walled and tight. I should also want double-walled hives.

Mr. Root—I think that bees in chaff hives will not be affected by cold nights. If the bees are to work in the sections at night the supers must be warm enough for them to do so.

Mr. Berg—I lose more bees in the cellar than in chaff hives, so I prefer to winter them in chaff hives.

Mr. Hilton—I have cushions on all of my hives. I think the cushions must be retained on the supers in order to have the bees draw out the comb. The supers must be tight or the bees can not work in them, and it will not do to put on supers when the brood-chamber is only half full of brood. The brood-chamber must be filled with brood and no honey, and the hives must be warm.

Mr. Beecham—I was led to use the Heddon hive so as to avoid the handling of so many frames. I would like to ask if Mr. Hilton has any trouble in getting out the first frame.

Mr. Hilton—None at all. I have self-spacing frames with thick top-bars.

Mr. Sillsby—I have no trouble in getting out the first frame; I use a block with a slope to it, and have thick top-bars. Neither am I annoyed with brace-combs.

Mr. Hilton—I leave a $\frac{3}{4}$ -inch space between the top-bars to prevent brace-combs.

Mr. Beecham—One must be a good judge to know when is the right time to put on supers.

Mr. Townsend—I use full sheets of foundation.

Mr. Root—One must have the hives tight so that the cold air can not get in.

Mr. Beecham—I have had trouble with bees that would

not store honey in sections, but would store it in the extracting combs.

Mr. Townsend—They will store honey in the extracting combs better than in the sections.

Mr. Hilton—I have had experience with both starters and full sheets of foundation, and the sections have been finished sooner when the full sheets were used.

PLAIN SECTIONS AND FENCES.

Mr. Coveyou—I like the fence separators best, as the queen does not like them.

Mr. Root—Three-fourths of the orders now are for plain sections with fence separators.

Mrs. Menold—I use a section plain all around.

Mr. Hilton—A plain section is one without the inset. I never had first-class section honey until I used plain sections. The sections must be taken off as soon as they are capt over or they will be travel-stained. The tiering-up must not be continued too long. The plain section without the inset has come to stay. The honey that sells to fancy trade is that secured by using plain sections and fence separators.

Mr. Berg—I used plain sections for the first time the past season, and like them the best.

Mr. Fox—I have sold my honey in plain sections in this city.

USING OLD SECTIONS—ALSKE CLOVER.

Mr. Root—Does it pay to use sections that have been used the year before?

Mr. Hutchinson—I think that if the old sections have been taken care of and kept clean they are all right to use again.

Mr. Hilton—I have put on sections that have been used before, but every year I use less of them. No sections ever come off as nicely as the first I put on—the first honey here is the best. I get better results when I use new sections, as the bees seem to work better in them.

Mr. Beecham—I have always used drawn comb in the sections. I take off sections before the buckwheat flow, as I do not want it to get mixed with the white honey.

Mr. Berg—I have used cleaned sections with drawn comb, and have found that the bees would get these combs uneven. I get the best honey from new sections, when I use full sheets of foundation.

Mr. Sillsby—I sold all of my white honey for 15 and 16 cents per pound. There are 100 acres of alsike clover near me, and the bees work better on it than on red clover.

Mr. Storer—I have had a fine lot of honey from alsike clover; bees like it the best.

EARLY FEEDING—WORKING IN SUPERS.

Mr. Sillsby—I would like to ask about early feeding to build up the colony.

Mr. Hilton—Begin to feed as soon as the bees begin to fly.

Mr. Hutchinson—I do not think that liquid feeding in the spring pays. A weak colony must not be stimulated in the spring; if this is done and a cold spell comes on then it's "good-by" to the colony.

Mr. Berg—I have had trouble with bees not working in the supers. I reduced the swarming fever by extracting—putting on a shallow super, then extracting the honey they stored in it, and afterward putting on sections. I put a new super underneath the one partly filled, being careful not to allow the upper one to become filled.

Mr. Hilton—I put an empty super underneath the one partly filled, and tier up just as soon as the super is $\frac{3}{4}$ full. Bees will not travel by an empty super.

Mr. Coveyou—I think it pays to put supers on early, so as to get the early flow.

SWARMING.

Mr. Berg—When bees have nothing to do they want to swarm. I would rear colonies from queens that do not swarm, as my experience has been that I get more honey from bees that do not swarm.

Mr. Beecham—If you run for extracted honey your bees will not swarm, but they will if you run for comb honey.

Mr. Berg—I had one colony that did not swarm, and they stored from three to four supers of honey every year.

Mr. Kaufman—I have no trouble with the bees swarming, as I run for extracted honey.

Mr. Kitson—I have had three queens in one hive, each queen having a part of the hive.

Mr. Berg—it is very difficult to keep the bees from swarming when producing comb honey. People should not eat comb honey, as the wax is not good to eat; it is indigestible, and is not made to eat, but to hold honey. Extracted honey is the best to eat.

Mr. Hutchinson—Extracted honey is more easily pro-

duced, and the outlook is good for it at present. The market is growing better all the time, and no bee-keeper who has kept a large number of colonies has made money unless he has run his bees for extracted honey.

Mr. Beecham—I would like to ask if the Hilton hive would stay packed.

Mr. Hilton—They are ready for use all the time—winter spring, or fall.

KEEPING ANTS OUT OF HIVES.

Mr. Beecham—I am bothered with ants.

Mr. Berg—I used tarred paper under the bottom of the hives to keep the ants out. I like the chaff better, the best, and ventilate them in warm weather, when the bees hang out.

Mr. Root—I use tar paper to keep the ants out of the hives.

Mr. Hilton—I use salt to keep the ants away. It will drive the ants away, but not the bees. I put the salt on the inside of the hives, on the bottom-board.

Mr. Kitson—I would like to know of something that will keep the grass and weeds down.

Answer—Salt will do this very well.

BEES AND FRUIT.

Mr. Root—What about that case near South Haven, Mich., where a peach-grower sued a bee-keeper for damages?

Mr. Rankin—The bee-keeper was sued by a peach-grower for damages to the amount of \$200. The records of the Department of Agriculture at Washington, D. C., showed that bees will not attack fruit with a whole skin. From the evidence shown at the trial the fruit-grower withdrew his suit. It seems that some of the early peaches were affected with a peculiar rot which attacked the fruit before it was ripe, and the bees work on this fruit.

Mr. Root—The same trouble occurred in the State of New York with the early cling-stone peaches. A suit came to trial there but the verdict was "no cause for action."

Mr. Berg—We have no bee-fighters in this part of the country. The fruit-growers want the bees near their fruit to fertilize the blossoms. Many of them spray their fruit-trees while in bloom, and some bee-keepers have lost half of their bees from this cause.

Mr. Hilton—A law was past while I was in the Legislature prohibiting fruit-growers from spraying trees while in bloom.

Mr. Kitson—I wish that law might be published in the bee-papers.

(Concluded next week.)

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

KINDNESS IN THE HOME.

I never could quite understand the biblical expression, "The small foxes destroy the vines." The fox has no love for the vineyard. The poultry-house attracts him far more. Neither vineyard nor grape is toothsome to Reynard, yet the truth taught in this small fox, and despoiled vine-field, is absolute. The true home is builded on real heart sympathy. Unless each feels for the other, what will keep back the cruel sarcasm, the unfeeling word, the taunting laugh? And are not these, one and all, the little foxes?

I have a dear home in mind—father, mother, two daughters. It is a home where the bitter word, or thought that prompts it, was never in evidence. Paul's grand words were ever heeded in that splendid home—"Let each esteem the other better than himself." I mind me of a beautiful winter evening. I was the fifth one in that home circle for the time. We were all talking in merry mood, except Edith, who was trying to manage a great volume of pictures. Her small slap and the big book were a great misfit. Tho not impatient, she turned the pages with no slight effort and trouble. Without any break in our converse, the thoughtful father past thru the large wide-open folding doors to the next room, quietly caught a suitable chair, and soon the myriad pictures were resting on this improvised book-stand, where it was easy to turn the great pages. It must have been a rich reward to that thoughtful father's heart, as his act was greeted with a sweet smile and hearty "Thank you." This was just one of a whole troop of kindly acts that so filled that home with sun-

shine that there was always some to spare, and we fortunate visitors ever carried a good quantity away when we past out of its doorway.

If Heaven ever does give a little piece of her very own precious self to this world, where all is not yet heavenly, it is in just such homes. The father never hears a wish from any of the loved ones, that his heart does not yearn to satisfy it. His best pleasure comes from the little planned surprises. Labor and effort that would vex and weary where no love sweetens the life, is now only and wholly pleasure. The mother-heart is even more alert. She is ever touched and moved by any wave of pain or trouble, and irksome labor, and even painful effort, are covered by her, if they but minister to the pleasures of the household. Christ raised the world,—is ever raising it to higher and higher thought and purpose—because he was willing and glad to give himself to it and for it. It is this Christ spirit of sacrifice that gilds the home. Children that breathe such an atmosphere must enjoy moral health in all its blessed fullness.

We have a cow in our airy barn and cleanly yard just back of it. She is of the pleasing fawn, so generally seen in the Jersey herd, and her bright eye has the nervous sprightliness of the breed. How pretty is the double ring of color that keeps guard above her mouth and nose. Gentle is she as the dove that coos hard by among the evergreens. She looks happy. I think she is. She ought to be. Good performance will hand over happiness if anything will. Our Jersey deals in good performance. For eight years she has given us a daily average of ten quarts of the most splendid milk. And such cream and butter—yellow as the golden-rod, and sweet as its nectar drops. Happiness is born of appreciation. Our Jersey never hears a harsh word. The milk-stool never serves but for a seat. When she sees me coming she greets me with an appreciative call which none other ever receives. She knows I give the care, and that I look carefully to her needs. There is a kind of good-fellowship between me and my Jersey that is not one-sided in its fruits. It is a delight to feed and milk her, which is done at just the same time each night and morning. It is a pleasure to plan for feeding her just what will be most appetizing and at the same time will push the white foam away to the very brim of the pail. Would the home circle be complete without such companions? Let us give the children such pets and begot in our children such love of these friends of the home, that the golden rule will be one of the trio whenever child and pet cow, horse or kitten are companions.

THE INFLUENCE OF HOUSE-PLANTS.

We may not all have costly paintings, fine statuary may be out of our reach, but there is a home adornment which costs but a trifle, and which transcends either picture or statue in real beauty. It is from God's hands, and so shows perfection in its fashioning. Our parlor now has a great sword-fern just by the west window. Near it is a very costly painting—one of Hill's incomparable touches showing the marvelous Yosemite. Yet were one—painting or plant—to leave for a day, I would give up the picture. Yet this plant has only cost a trifle except Mrs. Cook's daily and loving ministrations, and these are not given grudgingly.

Close by at another window is the dainty, exquisite palm—*cocos weddelliana*. The one is ever reaching out its refining influence in its great health, wondrous vigor, rich color, and incomparable grace. When tired, it is so restful to sit beside it. To be peevish or irritable in its presence would seem all inharmonious. The little palm so clean, delicate, and full of grace, is equally "a joy forever." Why are there so few of such gems in our homes? Our dining-room and hall have like treasures. Bereft of them the room would suffer indescribable loss.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and thus often leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one of the buttons, as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we have been furnishing to bee-keepers for a long time. It has a pin on the underside to fasten to the coat. Price, by mail, 6 cents each; two for 10 cents; or six for 25 cents. Send all orders to the office of the American Bee Journal.

Maule's (35 new things for 1931) Seed Catalogue

You should, by all means, have this most modern catalogue of modern times. It is brimful and overflowing with good things in vegetable, farm and flower seeds, flowering plants, fruits, bulbs, etc. It contains 35 novelties in vegetables and flowers never offered before, has 136 large pages, seven handsome colored plates and hundreds of illustrations. It gives practical, up-to-date cultural directions and offers many cash prizes. The first edition alone costs over \$30.00, so while we send it free to all customers, we must ask others to send 10 cents for it, which amount they may deduct from their first order. You will make a mistake if you do not write to-day for this the Novelty Seed Book of the year. Address, **WM. HENRY MAULE, Philadelphia.**

HOME-SEEKERS' EXCURSIONS.

On the first and third Tuesdays of each month the Chicago, Milwaukee & St. Paul Railway will sell round-trip excursion tickets from Chicago, Milwaukee and other points on its line to a great many points in South Dakota, North Dakota, and other Western and Northwestern States at about one fare. Take a trip West and see the wonderful crops and what an amount of good land can be purchased for a little money. Further information as to rates, routes, prices of farm lands, etc., may be obtained by addressing F. A. Miller, General Passenger Agent, Chicago, Ill. ☐

GENERAL ITEMS

Prospects Good for the Coming Season.

I am a beginner in the bee-business, and have five colonies of bees in the cellar, which seem to be doing well. The prospects for the coming season are good, and I think we will have plenty of white clover.

I have taken the American Bee Journal one year, and think I could hardly do without it, as I get so much valuable information from it. **C. M. LAWRENCE,**
Blackhawk Co., Iowa, March 7.

Winter Report—Long-Tongued Bees.

The season of 1930 was not a very good one for honey in this locality. I have not had a paying crop for three years, but look for better things the coming season. The indications for a good crop of white clover were good up to March 2d, but it turned cold on the 4th, after having been warm for a few days, and melted all the snow, which leaves the clover in bad condition. Bees wintered outdoors have had a number of good flights during the winter, but those in the cellar are not doing very well, being more uneasy than usual; more than a third of the 70 colonies in the cellar are spotting their hives, and I think there are many more dead bees on the floor than in former winters. I have been keeping a record of the bees swept up since Jan. 16th, also of the number of hives spotted, and will report on it later.

I have some of the long-tongued bees 18 and 19 mm., the latter of the five-lined stock. I shall watch the tongue matter next summer, as I am prepared to measure the tongues. **THEO. S. HIRLEY,**
Tama Co., Iowa, March 5.

Bees Wintering Well.

Bees are wintering well, are building up nicely now, and prospects are good for a honey crop; but sometimes we have dry weather that cuts us out. **T. B. BOWDYS,**
Milam Co., Texas, Feb. 4.

Hard Winter on Bees in New York State.

So far the 20th century has been the worst ever known for bees in this locality. There has been no weather for them to have a flight, and during the whole month of February it didn't thaw even once in the shade, with the thermometer from zero to 12 degrees below much of the time. The snow is from 4 to 10 feet deep in our roads, and the ice is from 18 to 22 inches thick on the ponds and lakes. Bees that survive will be of a hardy race—those wintering on the summer stands, at least. **G. M. DOOLITTLE,**
Onondaga Co., N. Y., March 6.

Report for the Past Three Seasons.

I am a man with a hard case of chronic fever. Two years ago a friend gave me, late in July, a colony of bees in a box-hive. They cast a swarm the next day, which I hived successfully in a Langstroth hive. Late as it was, they gathered enough honey for winter, and the next summer I divided them. The colony in the box-hive swarmed when I was away from home, and they never came back any more. I got 125 pounds of comb honey that year.

The next spring I purchased 12 colonies at \$3.00 each; that was a poor year for honey in this locality, and I got 420 pounds of honey (nearly all of which was dark), and increased to 22 colonies. One of these was queenless in the spring, so I began the last season with 21 colonies. White clover, basswood and buckwheat did nicely, but there was no fall flow to speak of. I secured 73 pounds per colony.

A 20th Century Catalog. It is not the fault of the seedsmen if the tables of the farmers at this season of the year are not abloom with colored illustrations of the products of the vegetable and flower garden. One of the largest and most attractive is "Maule's Seed Catalog, 1901." Its 136 pages are literally crammed with information about seeds that grow in which Maule sells. From it we learn that the concern is one of the largest mail-order houses in the world, paying out during the last 5 years, for postage, \$71,827.30. It also sells a number of novelties in the catalog, the two leading ones being the "Success" tomato, which is pronounced to be the best market tomato introduced to the American farmer and gardener, and the Snow White Dent corn, said to be the grandest milting corn in the world. Other new varieties are Maule's First Early cabbage, the Model muskmelon, the Snow White eggplant, unnamed French carrot, Imperial Giant sugar-corn, Maule's unnamed lettuce, Excelsior Tree egg-plants, the Prodigious pea, and others. In fact, the largest list of new things we have member to have seen in any one catalog. It would be an educator in any family, and can be had free by our subscribers for the asking; others must send in cents for it. Published by **Wm. Henry Maule, Philadelphia, Pa.** Please mention American Bee Journal when writing.

spring count, and increased to 35. Some one robbed one of these, so now I have only 34. I winter the bees on the summer stands, and the only loss I have sustained so far is the one queenless colony last spring, and they are all in good condition now. I intend to keep increasing until I get enough.

The American Bee Journal is "loss of the job." I do the work. C. H. BENSON.
Calthoun Co., Mich., Feb., 28.

Tin Cans vs. Barrels for Honey.

J. H. Martin says freight-rates on honey in tins cased, from California to the East, are \$1.10 per 100 pounds; on honey in barrels \$1.30 per 100 pounds. The editor is a tin-can man, and, calmly says, "Comment is unnecessary." Now, ye editor, we won't comment, but listen:

Freight-rates on honey in tin cans cased, from Apalachicola River points in Florida to Boston, New York, Philadelphia, etc., are \$1.35 per 100 pounds; on honey in barrels 78 cents per 100 pounds. Arguments in favor of barrels vs. tin cans for shipping honey now in order. Comments received.

M. W. SHEPHERD.
Franklin Co., Fla., March 4

("Comment is unnecessary!")—EDITOR.]

Bees in Splendid Condition.

We have so far had a very pleasant winter—only three zero days in January and five in February. There were ten days in January and three in February when the bees could take flights; they are having a fine flight today, and every colony seems to be in the best of condition.

When we have another warm spell I intend to overhaul all my colonies, and properly adjust them. WM. STOLLEY.

Hiatt Co., Nebr., Feb. 27.

Bees Wintering Nicely.

My bees have wintered nicely, and the prospects are better for a good crop of honey this season. W. W. McNEAL.

Scotio Co., Ohio, March 19.

Prospects Bright—Controlling Swarming.

The rain is pouring down, and the country in this vicinity never look better. All the farmers are rejoicing over the prospects of a splendid season, and all is fine for the bee-keeper as well as the rest.

The last of next month I expect to requen all of my colonies, and try to control swarming, if possible. Last year we had but 11 swarms, and I notice that one of the mother colonies is now very weak. I bought some queens from Texas last year, which were fine layers, and I managed the colonies so that no swarms issued after the prime swarm. A little while before swarming-time I requen all colonies, giving them a young laying queen, so I am not very often troubled with swarms; tho sometimes they will swarm in spite of all that I can do. HARRY L. HEWITT.

San Joaquin Co., Calif., Feb. 23.

1900 a Poor Season.

Last season was a very poor one for bees here. There was not much for them to gather after July 1st, so a great many of them went into winter quarters with very little to live on thru the winter, and now I hear that over 60 percent are dead. Mine are all right so far; I fed them last fall, and expect to feed again in the spring. M. H. VOYT.

Nemaha Co., Kans., Feb. 25.

Bees Wintering Nicely Good Report.

My 19 colonies of bees seem to be very quiet, and I think they are wintering nicely in the cellar. The bottom-boards are nailed tight to the bottoms of the hives, the entrances are open clear across, and the covers are shoved forward about two inches, with a cloth over

PAN AMERICAN EXPOSITION.

Nothing since the World's Fair, at Chicago, in 1893, has elicited the widespread interest that is manifest, all over the world, in the Pan-American Exposition, which is to be held in Buffalo, from May 1 to Nov. 1, 1901.

The purpose of the Exposition is to illustrate the progress of the countries of the Western Hemisphere during a century of wonderful achievements, and to bring together into closer relationship the people composing the many States, Territories and Countries of the three Americas. Acting under proper authority, the President of the United States has invited all the Republics and Colonies of the American Hemisphere to join in commemorating the close of the Nineteenth and beginning of the Twentieth Century, by holding this International Exposition on the Niagara Frontier.

For this important event, the Nickel Plate Road has issued an attractive, descriptive folder—pamphlet, elaborately illustrating the Pan-American Exposition, the buildings and grounds.

The Nickel Plate Road is the short line between Chicago and Buffalo, and affords competent train service from Chicago to Buffalo, New York City, Boston, and all points East, with trains of modern equipment, on which no extra fares are charged; also dining-car service of the highest order. It affords meals in its dining-cars on the individual club plan, ranging in price from 35 cents to \$1.00.

Call on any ticket agent for Pan-American folder of the Nickel Plate Road, or address John Y. Calahan, General Agent, 111 Adams St., Chicago.

Parties desiring hotel or rooming accommodations at Buffalo or Niagara Falls, during any period of the Pan-American Exposition, are invited to apply by letter or otherwise to F. J. Moore, General Agent, 21 Main St., Buffalo, N. Y. No. 4—12, 13t.

on this vehicle. The quality outweighs the price. The balance is always in your favor on our line. Why? Because we make the highest grade of goods and sell them to you direct at factory prices, saving you the two profits of the jobber and dealer. Besides all this we send any vehicle on 10 days free trial. If not entirely satisfactory, return it at our expense. Can you ask more? Write for catalog.

Kalamazoo Carriage and Harness Company,
Box 53, Kalamazoo, Mich.

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal
one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size stone for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost.

No man is well-equipped unless he has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired bevel by inserting the beam of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on an steady the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding **Round-Edge Tools**, the tools in the standard are used instead of the notches.

GEORGE W. YORK & CO., 114 & 116 Erie St., Chicago, Ill.

the brood-frames. They generally winter well when packed in this way.

I had 10 colonies last spring, increased to 19, and secured about 150 pounds of comb honey. They went into winter quarters strong and seemed to have plenty of good honey, so I am looking for a good harvest the coming season, as we have plenty of sweet and white clovers.

The "Old Reliable" is a regular Thursday visitor; long may it live!

W. A. HARRINGTON.

Boone Co., Ill., Feb. 25.

Bumble-Bees in Winter—Prospects Good.

For a number of years. It has been, and still is, a mystery how bumble-bees get safely through the winter. If some one will tell me how they get there I will tell where to find them. During the winter months a little round ball can be found underground, on the inside of which is a white, downy bumble-bee, apparently about ready to emerge. About the time of the woad-herb bloom the occupant comes forth and partakes of Nature's best. This round ball, so far as I can tell, is precisely the same as those formed by the tumble-bug.

Bees are wintering splendidly, and the prospects are good for the coming season.

FRANK COVERDALE.

Jackson Co., Iowa, Feb. 25.

Bee-Keeping Experiences.

About six years ago I bought two colonies of black bees, paying \$5 each for them in July, and from one of these I obtained a super of nice honey that season. After wintering them in the cellar, from whence they came in vigorous condition in the spring, they gave an increase of three colonies, and, if I remember rightly, three swarms of nice white honey.

About two years ago I bought 11 more colonies from a bee-keeper, and as I wanted to have them in time to put into winter quarters, the arrangement was that he should take them to town, and should notify me when he did so. It was about five days after he sent me word before I could go after them, but when I finally did so I found that they had been moved during a rain and sleet storm, and placed in a wood-shed covered with some old rain-soaked carpet. The hives and carpet were an icy mess, as well as the bees. I hauled them home—a distance of 30 miles—placed them in the cellar, which was dry and well ventilated, and after raising the covers, and also the hives from the bottom boards, in order to give them a chance to thaw and dry, I left them to their fate. After three or four days I went down to see how they were getting on, and found one colony a mass of wet, dead bees, and so they kept going until the whole 11 colonies were dead before it was time to put them outdoors in the spring. The next summer I bought 22 colonies, sold about 20, and obtained a few hundred pounds of honey.

Last spring I took 56 colonies from the cellar, and put the same number in again in the fall. Three dwindled away, leaving only 53

in condition for business. In May I chimed 10 colonies at \$5 per colony. I received and accepted the appointment as census enumerator, and was thus compelled to be away from home during the month of June. My son, 13 years of age, with the assistance of the hired man, caring for the swarms, of which there were only 12 or 15 during the entire month. During July there was a contagion of the swarming-fever, and altho we had tried to prevent swarming by giving more room, cutting out queen-cells, giving ventilation and using every method we had ever heard of, about 70 swarms emerged, which we counted, their increasing our number only about 30. We secured over 1,800 pounds of honey, 1,000 pounds being comb. The total crop was worth \$232, figuring what we consumed and kept for winter use at the same price as what we sold. We put 100 colonies into the cellar, having brought enough to make that number. Our cellar is well vented, having an open chimney extending from it. Some of the swarms were very light when put in, and we placed them at the top, putting supers over them containing light-weight sections. Yesterday I went into the cellar and found a lot of dead and crawling bees on the cellar floor, and a very uneasy condition prevailing. I would like to know the cause of this. Have some of the colonies starved out, or is the cellar too warm? Not having a thermometer I can not give the temperature, but I judge it is about 45 or 50 degrees. H. W. CORNELISON.

Washburn Co., Wis., Feb. 16.

CONVENTION NOTICES.

Chicago.—The next regular meeting of the Chicago Bee-Keepers' Association will be held Thursday, April 4th, at the Briggs House, Chicago, from 1 p.m. until those present get tired and quit, which is usually at 3:30 p.m. A feature of the meetings lately has been for all present to dine at 5:30 in a company. All are urged to be present and help us all have a good, old-fashioned time. HERMAN F. MOORE, Sec.

Utah.—The Utah Bee-Keepers' Association will hold its regular spring meeting April 5th, at 10 o'clock a.m., in the City and County Building at Salt Lake City. All are cordially invited. We expect to get out a treatise or circular, the object of which will be to give the best and quickest method to discover, cure, and prevent disease among the bees, and the best way to protect them from their enemies. It will also contain other matter for the benefit of the industry, including our State law. We will be pleased to receive communications from any of our bee-keepers, upon any subject, and the lines indicated. Address, Pres. E. S. Lorey, Salt Lake City, Utah, or J. B. Fagg, Sec., East Mill Creek, Utah.

TWENTY MILLIONS IN GOLD

From Alaska during the year 1900.

Five millions of this came from the Nome district. Government officials estimate the output from the Nome district will be doubled the coming season. The Bluestone, Kougark and Pilgrim rivers have been found very rich. There is hardly a creek from Port Clarence to Norton Sound in which the precious metal is not found, and hundreds of creeks unsuspected. A rich strike has been made on the Yellow river, a tributary of the Kuskokwim.

For full information regarding routes, steamship accommodations and rates to all points in Alaska, address C. N. Southern, General Agent, Passenger Department, C. M. & St. P. R'y. 95 Adams Street, Chicago. 13A3t

Tennessee Queens!

Fine lot of Choice Tested Queens reared last season, daughters of select imported and select golden queens, reared 3½ miles apart, and mated to select drones, \$1.50 each; untested warranted queens, from same breeders, either strain, 75c each. No bees owned nearer than 2½ miles. None imported within 3, and but few within 5 miles. 2 years' experience. Discount on large orders. Contract with dealers a specialty. JOHN M. DAVIS, LA2ot Spring Hill, Tenn.

Please mention Bee Journal when writing

Worth \$25. B. H. Greider, the well-known poultry-breeder of Florin, Pa., whose card will be found elsewhere in this issue, recently received a letter from a customer who enclosed stamps for several copies of Mr. Greider's catalog for his triceps, saying that the copy he had received was worth fully \$25 to him. It is a most valuable book, handsomely illustrated, and containing full descriptions of all the leading varieties of poultry. Mr. Greider's farm at Florin is one of the best stocked poultry establishments in the country. He has been a careful student of advanced methods, and by careful breeding has produced as fine a lot of fowls as will be found anywhere. Moreover, having a large farm, his fowls are not cooped up in little pens, but have the good range necessary to health and vigor, and the production of fertile eggs which hatch chicks that live and grow. It is for this reason that Mr. Greider's customers always are so well satisfied with their purchase from him. Send 8 cents for this valuable book. It is full of money-making hints. Circulars free. Please mention the American Bee Journal when writing.

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia*)

...FREE AS A PREMIUM...

The A. B. C. of Bee-Culture says of it: "This is a valuable plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height and bears large, clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado where it is said to furnish large quantities of honey."

We have a few pounds of this Cleome seed, and offer to mail a 3¢ seed package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00; or ¼ pound by mail for 40 cents.

GEORGE W. YORK & CO.

118 Michigan St. CHICAGO, ILL.

Good Instruments.

Don't confuse those instruments with cheap "laminated counter" offers. They are high grade, fully guaranteed, instruments FOR THE BEST TANS.

VIOLIN—Amati model, choice of 5 tones, dark brown, light red or amber, Italian violin trimmed, Brazil or pearl shell, full leather bound canvas back, extra of 50 strings, etc., worth \$20. My Price, \$6.27.

GUITAR—Solid rosewood, standard neck, solid, 14 fret, ebony finger board, best quality patent head, full leather bound canvas back, regular price \$18. My Price, \$5.50.

MANDOLIN—Solid rosewood, 10 fret, celluloid front, veneered head piece, handsomely inlaid, elegant finish. Polished, 14 fret, head, engraved tail-piece. Worth \$15. My Price, only \$7, with leather bound, extra of 50 strings and tortoise pick. Send for circulars of high grade musical instruments of all kinds.

Charles A. Morse, Auditorium, CHICAGO.
Please mention Bee Journal when writing.

The Emerson Binder.

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send with the Bee Journal for one year (both for only \$1.00), a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W. YORK & CO.,
118 Michigan Street, CHICAGO, ILL.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, March 26.—The choice grade of white comb honey sold at 10 cents, with supply about equal to the demand; all other grades are slow of sale at the following range of prices: Fair grades of white, 14c to 15c; fair ambers, 12c to 13c; mixt colors, 10c to 11c; buckwheat, 9c to 10c. Extracted, white, ranges from 7c to 8c; amber, 6c to 7c; buckwheat, 5c to 6c. All of the extracted honey is of good quality and in favor in the market. The lowest figures in either of the colors applies to the sour, or off-flavored, and unripened. Beeswax, 20c.

R. A. BURNETT & Co.

NEW YORK, March 19.—Our market is virtually bare of comb honey, and there is a fair demand for all grades. Fancy white is still selling readily at from 15c to 16c. No. 1 white at from 13c to 14c; amber at from 12c to 13c; buckwheat, 10c to 11c, according to quality and style of package. As to extracted, the market is quiet and inactive, and a certain amount will have to be carried over again. Prices are declining somewhat, and if the honey market is to be active, concessions will have to be made. We quote: California white, 7c to 7½c; light amber, 6c to 6½c; other grades and Southern, 5c to 7c per gallon. Beeswax very firm at 24c to 25c, and for exceptionally fine yellow, 27c.

HILDRETH & SEGELKEN.

BUFFALO, March 21.—Much better demand for fancy comb at 15c to 16c; extras, 17c; common, dark, etc., 10c to 14c. Extracted, 6c to 8c, and new in market. BATTERSON & Co.

DETROIT, Mar. 23.—Fancy white comb, 14c to 15c; No. 1, 14c to 15c; dark and 14c to 15c. Extracted, white, 6c to 7c; amber and dark, 5c to 6c. Beeswax, 27c to 28c. M. H. HUNT & SON.

CINCINNATI, March 21.—The demand for comb honey is nearly over, the stock of it also well cleaned up. Fancy white brings yet 10c. Extracted is in fair demand; dark sells for 5c; light better grades bring 6c to 7c; fancy white cleaver better grades bring 6c to 7c; fancy white cleaver at 7c to 8c. C. H. W. WEBER.

KANSAS CITY, Mar. 23.—Receipts light; demand normal at steady prices. Fancy white comb, 15c to 16c; no amber on market. Extracted, 6c to 7c. Beeswax, 24c to 25c. W. R. CROMWELL, Owner.

Successors to C. C. Clemens & Co.

ALBANY, N. Y., March 23.—Honey market is slow on all grades of comb honey. Extracted, white, 7c to 8c; dark, 5c to 6c. H. R. WRIGHT.

BOSTON, March 21.—Fancy No. 1 white in cartons, 17c; A No. 1, 16c; No. 1, 15c to 16c, with a fairly good demand. Absolutely no call for dark honey. Extracted, white, 6c to 7c; 8c; light amber, 7c to 8c. Beeswax, 27c to 28c. BLAKE, SCOTT & LEE.

SAN FRANCISCO, Feb. 6.—White comb 13c to 14c; amber, 11c to 12c; dark, 8c to 9c. Extracted, white, 7c to 8c; light amber 6c to 7c; amber, 5c to 6c. Beeswax, 26c to 27c.

Considering the light output of honey last spring from California apiaries, present offerings are of tolerably liberal volume and are most of amber grade. The market is slow at the quotations. It is reported on good authority that adulterated and imitation honey is being dealt out in considerable quantity, which accounts for the slow demand for the very limited business doing in the pure article.

The Danzenbaker Hive.

THIS HIVE is rapidly gaining favor, especially in the Eastern States, where tall sections and closed-end frames are to a considerable extent; and within the last year or so the Danzenbaker system has been working its way into California, Oregon, and even into Cuba. At the Paris Exposition the hive was awarded a gold medal, and at some of the honey exhibits in this country the comb honey from it has carried off the first prize. Some of the finest honey we have ever seen was produced in Danzenbaker sections; and in the opinion of those who have given the hive and system an extended trial, there is nothing to equal it for the production of a fine article of comb honey. Indeed, in some markets comb honey in Danz. sections commands one and sometimes two cents more per pound than other fancy honey.

Mr. Danzenbaker has long been an advocate of warm supers and warm hives; for he has always insisted that, for the production of comb honey, the super and hive must be warm in order to do the best work in wax-building. To a very great extent the Danzenbaker hive is double-walled; and the sections in the super are especially protected by a special paraffine mat which goes with every hive.

The brood-chamber itself has the same dimensions as the regular 10-frame box-tailed Langstroth hive, except that it is shallower; that is, it takes 10 closed-end brood-frames 7½ inches deep and 17 inches long. Each brood-frame is supported by a pivot in the center of the end-bars, so that it may be readily reversed. These brood-frames retain all the advantages of frames peculiar to this class; viz., being reversible, they insure the building of combs to the bottom-bar; as there is no opportunity for air-currents around the ends of the frames, combs, as a rule, are built clear out to the end bars. This one feature makes them warmer for winter. When a division-board is used on each side we have, practically, a dead-air space around the ends and sides of the brood-nest.

The Danz. brood-nest has the same capacity as the 8-frame Dov. hive—a capacity that has generally been recognized as the best for the production of comb honey. But Mr. Danzenbaker has gone further by making his brood-nest shallower and wider—increasing the amount of surface for the super, and bringing the brood itself—a feature which many consider important—closer to the surplus.

The Danzenbaker brood-chamber can be used, with any of our 10-frame supers, either comb or extracted; with any of the 10-frame covers, bottoms, or hive-stands, or with the 10-frame Jumbo hive. There are four patents on the Danz. hives and fixtures.

NOTICE.—The Danzenbaker hive is not made in the 8-frame widths.

WEEKLY

◆◆◆ APRIL ◆◆◆

BY EUGENE SECOR.

Did you hear the robin piping,
Calling for his mate?
He has just returned from Southland—
But, perhaps, she's late.
He tells us the plum-trees will soon be in white
To witness his vows and the bird marriage-rite.

Did you see the prairie crocus
Held in childish fist
Tight as lover holds his sweetheart
At the evening tryst?
This brave little flower opens early to fling
Its largess of gold on the honey-bee's wing.

Maples blush with ruddy blossoms
E'er the frost is gone;
And the showy golden willow
Brightens on the lawn.
The barn-fowls are noisy, proclaiming each day
The debt which they owe and are trying to pay.

Intersperst with cheery sunshine
Weeping clouds appear,
But, together, they encourage
Life with hope and cheer.
"The winter is past," every sleeping bud cries,
And seeds burst their caskets, determined to rise.

Queen-Clipping Device Free....

The MONETTE Queen-Clipping Device is a fine thing for use in catching and clipping Queen wings. We mail it for 25 cents; or will send it FREE as a premium for sending us ONE NEW subscriber to the Bee Journal for a year at \$1.00; or for \$1.10 we will mail the Bee Journal one year

and the Clipping Device. Address,
GEORGE W. YORK & COMPANY,
Chicago, Ill.

Long-Tongued Bees

ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers (with \$4.00.)

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation—"first come, first served"—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

28 cents Cash
paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 28 cents a pound—CASH—for best yellow.

low, upon its receipt, or 30 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO.

Best White Alfalfa or Basswood Extracted Honey

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are boxt.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

No. 14.

* Editorial Comments. *

Freight-Rate on Comb Honey. We understand that there is to be an attempt made to raise the freight-rate on comb honey, one railroad company desiring to make the rating *double first-class* on comb honey in boxes with glass fronts, *whether the glass is exposed or not*. The present rating is 1½ times 1st class. The proposed raise is "daunting it on a little too thick," we think, and the bee-men, the commission men, and the bee-keepers-supply men should line up and see if something can not be done to prevent such a prohibitory rating. Really, such a rating would well nigh strangle the honey-business from a shipper's standpoint, especially on long hauls. For instance, the rate from California points to Chicago would be \$6.00 per 100 pounds, making it impossible for Western producers to market their comb honey in the Central or Eastern States. Such an advance in freight would injure the bee-men by making their business unprofitable, the commission men by greatly decreasing consignments, and the supply men, directly, by tending to drive the glass-front shipping-case out of the market; and indirectly by making the honey-business so unprofitable as to greatly curtail the demand for all lines of supplies.

Of course, the rating of "1st class" on shipments in close boxes will still remain, but that will be of little value from the fact that honey can not be exposed for sale in such boxes, which would necessitate shipping in one kind of a box, and repacking in another kind at destination.

We consider the proposed move a great injustice to a class of men who deserve better treatment. There should be sent in at once earnest protests from every one interested, as far as possible. Especially can the large commission houses present the matter of injury to shipments in glass-front boxes as compared with that to close packages, and an exhibit of that kind would have considerable weight, especially as it can be shown that the glass-front box is the safer package, on account of the contents being in plain sight, thus insuring safe handling.

The next meeting of the Western Classification Committee will be held May 7th, at Hotel del Monte, Monterey, Calif., so that petitions and protests against the threatened raise in freight-rate on honey should be forwarded at once to Mr. J. T. Ripley, chairman Western Classification Committee, Room 604 Great Northern Bldg., Chicago, Ill.

Eating Honey and Butter.—A Stray Straw in Glensings in Bee-culture reads thus: "Dr. Pauchet, La Nature says, replaces cod-liver oil with butyronil, composed of two parts of fresh butter and one part of honey, beaten together. He says it is more readily accepted by children—a thing not hard to believe."

Editor Root then follows with this comment: "I remember my mother used to give me honey and butter when I had a cold. If there is any virtue in such a combination it might be a good idea for us parents to give our children bread and butter and honey, and lots of it. 'Honey and butter shall he eat,' the good Book says, and its advice is always good."

This reminds us that a certain family of our acquaintance informed us recently that they had eaten more honey than usual the past winter, and had been much healthier in consequence thereof. We haven't the least doubt that if more whole families would consume more honey in their regular daily diet they would all feel much better in every way.

Granulated Sugar and Glucose.—Mr. Thos. Wm. Cowan, editor of the British Bee Journal, but now residing in California, sent us the following communication early in January, but owing to our "deluge," and also moving to our new location, it was overlooked until a week or two ago:

EDITOR AMERICAN BEE JOURNAL.—On page 810 of the American Bee Journal for 1900, alluding to granulated sugar, Mr. E. E. Hasty endeavors to explain what he thinks I mean when I say "much of the granulated sugar of commerce is adulterated with glucose." Altho as a rule I do not notice criticisms, recognizing the right of every one to his opinions, and do not care to be drawn into any controversy respecting such criticisms, yet in this case, having a pleasant recollection of a personal visit to and talk with Mr. Hasty, I think it is due in courtesy to him to explain that I meant exactly what I said, because glucose is found in commerce both in the liquid and solid state.

On page 760 (1900) it will be found that, in explaining how glucose was made, I said, "The solutions are evaporated to a syrup consistency and sent into the market under the names of glucose, corn syrup; or to dryness, the solid product being known in commerce as grape-sugar." It is this dry glucose or grape-sugar that is used to adulterate granulated sugar, "the very dry white sugar" which Mr. Hasty alludes to. It is difficult to detect the adulteration by simply looking at the sugar. Raw or brown sugar is similarly adulterated. The presence of glucose when mixed with raw or refined sugar may be generally known by paying attention to the following points:

1. Sugars mixed with powdered or granulated corn glucose, on solution in water invariably leave white particles of glucose undissolved.
2. On submitting a commercial sugar containing glucose to the polariscope test, it will be seen that the reading does not remain constant, but gradually becomes less until a point is reached when the deflection of glucose when mixed with raw or refined sugar may be generally known by paying attention to the following points:

There are other methods of analysis, but they are only suited to the chemist's laboratory, and would not interest your readers. I can assure Mr. Hasty that it is not at all uncommon to find both raw sugar and refined dry granulated sugar adulterated with glucose.

With respect to pollen in honey, I can only say that in the large number of samples that I have examined, more or less pollen was found in every instance, and the presence of pollen-grains has frequently assisted me to determine with accuracy the source of the product.

If, and when, I have the time and inclination I should like to criticize Prof. Cook's criticisms of my book, "The Honey-Bee," but altho I have a personal regard for him, I do not find that he has adduced anything which would cause me to alter any of my views expressed in that book.

Yours truly,

THOS. WM. COWAN.

To Drive Ants from the Lawn.—Fine coal ashes sprinkled about the burrows of ants will cause them to leave. Ashes may be used on the lawn without injury to the grass. Sifted ashes are best, but those fresh from the stove, shaken from the stove-shovel, will answer the purpose very well. April Ladies' Home Journal.

Shall Bees Be Taxed? is a question that arises every now and then. Opinions differ. If one were to judge from what appears in the bee-papers on the subject, one would be likely to conclude that the great mass of bee-keepers were of the opinion that bees should not be taxed; because those who hold such opinion have a feeling that they are wronged by such taxation, and one who feels himself wronged is more likely to speak out than one who is satisfied with things as they are. One of the strongest presentations of that side of the case appeared in the Progressive Bee-keeper under the signature of D. L. Tracy. Mr. Tracy takes the ground that they should not be taxed unless the tax be refunded in years of failure. In such years an assessor can not fairly value a colony of bees. But he rightly says that such a proviso would lead to great complication; hence, bees should not be taxed at all.

Unfortunately this reasoning would apply to other things as well as to bees. A farmer may have a failure of crops, but he is expected

to pay his taxes all the same. If his bees are to be exempt because in some years they make no return, then his swine should be forever exempt because some years the cholera strikes them.

Those who believe with Mr. Tracy probably reason something like this: "There are years in which my bees not only pay me no profit, but are an actual expense, so that I would be better off at the end of the year if I had no bees. Manifestly I should not pay taxes on a thing of no value, and as the failure may occur any year, the easy way out of the difficulty is to have the bees exempt from taxation every year."

This has a somewhat reasonable look on the face of it, but one may imagine an assessor replying something like this: "Everything is ascertained according to its valuation, not according to its profitability to the owner."

"But," says the bee-keeper, "this year if the bees yield no harvest they are of no value, and should not be taxed."

"At what price do you sell colonies of bees in years of failure?"

"Why, just about the same as other years."

"Then they have a marketable value, and rightly, because even altho they may yield no return you do not give them away for nothing, holding them of value because of the possibility of what they may do in the future. And you seem to lose sight of the fact that you already have reduction of taxes because of the uncertain character of your bees. If you could count on getting each year straight along more than \$10 from each colony, as you did one year, then bees would readily sell for a much higher price than now—perhaps three times as much—and your tax on them would be three times as much. But the very fact that bees are uncertain property brings down their value, and so their price. If you insist that no tax should be paid in a year of failure, then in a good year when the profit on a colony of bees is as much as the profit on a cow, you ought to be willing to pay cow-tax on bees. When you are ready to give away bees for nothing, it will be time for you to say they have no value."

Mr. Tracy closes by saying, "I believe that all property should be taxed. But I do not believe from my experience that it would be right or justice to call bees taxable property." Which is equivalent to saying that bees are not property, or else there is a direct contradiction.

A New Honey-Eater.—Mr. Walter R. Ansell, of Ramsey Co., Minn., has sent us a sketch of a little animal which has been recently discovered in western Australia. It has been named *Tarsipes Rostratus*, and, tho only as large as a common field-mouse, belongs,

like the kangaroo, to the Marsupial order animals that carry their young in a pouch. It enjoys the unique distinction amongst mammals of obtaining its living exclusively by robbing flowers of their nectar with its long, thread-like tongue.

We have reproduced our new honey-loving friend for the benefit of our readers.

"The Best Article" that was ever published in the Review it would be difficult to point out. I doubt, however, if very many better ones have been published than the one by S. D. Chapman, that appears in this issue. It is somewhat lengthy, but not more so than is warranted by the magnitude of the subject. There is more in that article

than appears on the surface. The exact methods described may not be suited to many readers, but the thoroughness with which the writer has studied out the conditions of his locality, and devised a system of management adapted to those conditions, furnishes an encouraging example for us to follow."

This is what Editor Hutchinson says of the article by Mr. S. D. Chapman on page 215 of this number of the Bee Journal.

* The Weekly Budget. *

TO OUR DELINQUENT SUBSCRIBERS.—We often wish we could sit down in the homes of all our subscribers who are in arrears on their subscription to the Bee Journal, and try to explain to them that in all fairness to us and to themselves they ought to do their best to pay at least all arrearages, and if possible a year in advance. It should be remembered that our expenses in connection with issuing this journal are regular, and must be met. We can not put off our paper house, our printer, or our employees, with promises—they all must have their money. Hence, it is absolutely necessary that we should have the cash due on subscriptions in order to meet the necessary and constant expenses from week to week.

After we have favored several thousand subscribers by sending to them the Bee Journal for over two to four years without receiving any remittance, nor any acknowledgement of our requests to them to pay their subscriptions, we feel that we are justified should we decide to take some other means in order to hear from them. While we would like to have every bee-keeper read the American Bee Journal regularly, we would not willingly and knowingly continue to send it to any one who does not want it. But we must insist that all arrearages, if any, be paid. We shouldn't think that any one would wish to discontinue a paper of any kind without being clear on the publisher's books.

So many of us are careless about these matters. Of course, no one really intends never to pay his subscription. But do you know that when several thousand subscribers owe for say an average of three years at only one dollar, it amounts to a very large sum? And is it right that the publisher, who has faithfully furnished the paper right along, should be compelled to go without that much-needed and very large sum, which belongs to him, and which could just as well as not be paid? for it means only a few dollars to each one who owes, but in the aggregate, to the publisher, it means the difference between a small profit and a big loss!

Reader, are you in arrears on your subscription to the American Bee Journal, or to any other paper that you are reading? If so, will you not do the proper thing, and "pay that thou owest?"

THE HUNT FOR ERRORS in magazines, or in any publication, for that matter, is an interesting and profitable investment of time. Every article that is published in the Ladies' Home Journal, for instance, is read at least four times in manuscript form, and all statements of fact verified before it goes to the printer. Then it is read and revised by the proof-readers; goes back to the author for his revision; is re-read by the editors three or more times, at different stages; and again by the proof-readers possibly half a dozen times additional. Thus, each article is read at least 15 and often 20 times after leaving the author's hands until it reaches the public eye. But with all this unremitting vigilance, errors of the most obvious kind occasionally escape observation until perhaps the final reading, but it is rare, indeed, that an inaccuracy hides itself in the pages securely enough to go thru that magazine's edition.

The improvement in the proof-reading of most of the bee-papers is encouraging. Yet there is still room for the exercise of more care along this line in nearly all the periodicals devoted to bee-keeping, the old American Bee Journal included.

THE ROCKY MOUNTAIN BEE JOURNAL is the name of the latest claimant to the patronage of the bee-keeping public. It purports to be published "For Colorado and the Great Inter-Mountain Region." It is to be issued monthly, is neatly printed, and presents a good general appearance.

Convention Proceedings.

Report of the Michigan State Convention.

BY WM. G. VOORHEIS.

Continued from page 203.

BEE-PARALYSIS—SPRING DWINDLING.

Mr. Berg—What are the symptoms of bee-paralysis and what is the remedy? Can it be cured without changing the queen?

Mr. Root—There are different kinds of bee-paralysis, or it acts differently in different locations.

Mr. Berg—The bees look shiny, and seem to be shaking or trembling.

Mr. Root—In the South the disease is worse than in the North. When the queen is taken away they do better.

Mr. Kitson—I think my bees had that disease early in the spring.

Mr. Hilton—It is the result of inflammation.

Mr. Chapman—I have not been bothered with it in my apiary.

Mr. Root—The bees that are not affected will put the sick ones out of the hive.

Mr. Rankin—I have had no experience with this disease. I have tried to introduce it among bees, as an experiment, with queens and combs sent from the South, but did not succeed. I do not think that bee-paralysis will do much harm so far north.

Mr. Hutchinson—Nothing has been said about it for the last two years.

Mr. Kitson—I know what spring dwindling is: I lost one colony by it.

Mr. Kaufman—I lost a dozen colonies in that way. I cured them by changing them around, putting them in the place of healthy colonies.

Mr. Kirkpatrick—I do not think that the young bees have it: only the old ones are affected.

Mr. Root—When the bees begin to store new honey the disease disappears.

FOUL BROOD.

Mr. Hilton—I have a letter from C. A. Huff about getting a law past against foul brood.

George Jaquays—I got colonies with foul brood from East Jordan; it destroyed every colony I had but one.

Mr. Kirkpatrick—Four years ago in the spring I ship 125 colonies of bees from Indiana. I also took 67 colonies from a bee-keeper in this State to keep on shares. These last had been wintered in pits; I took them home, and afterward found that 37 of them had foul brood. I went all over the neighborhood but found no foul brood anywhere except in my apiary, and I burned all colonies thus affected. The next year I bought more colonies, but found that they also had foul brood, and I destroyed them. I lost 220 colonies all together.

Mr. Rankin—I do not think it necessary to destroy the colonies by burning them. The disease can be cured, but we must be protected from the bee-keepers who are careless to regard it. I think a law should be past similar to the one in effect in Wisconsin. They have the disease under control in that State, and I think that when colonies are affected with foul brood and ordered destroyed by the foul-brood inspector, the bee-keeper should be compensated, as live stock is compensated for. We ought to have a State inspector. When I find a colony affected with foul brood I mark the hive with a capital "B," and put a ring around the letter. Foul-brood germs can endure a great amount of dry heat, but can not live thru a very high temperature of moist heat. My cure for the disease is as follows: Scrape the hives, burning the scrapings—then swab out the inside with kerosene. Set the brood-chambers one above another, then set fire to them, and when the blaze comes out of the top put on a cover to smother the fire. Next seal the hives, frames, etc., with a solution of corrosive sublimate— $\frac{1}{2}$ ounce of corrosive sublimate to one gallon of water, putting them all into a tank of this solution, and thoroughly washing them in it. Carbolic acid can be used, if preferred. Care must be taken to see that no honey gets on the ground, as there is danger of other bees getting it. It is well to soak the hives, etc., about 30 minutes in this solution, and to care to burn the brood. The combs can be melted

into wax, and if there should be any honey in the combs, it can be extracted, and heating it will destroy the germs.

A motion was made and carried that Mr. Rankin, Mr. Bingham, and Mr. Hilton, act as a committee before the Legislature, to get the foul-brood law past. The committee must have the help of the bee-keepers in this State, and each one was requested to write a letter to his or her representative or State senator, asking them to support the passage of this law.

LARGE YIELDS OF HONEY.

Mr. Root—I understand that Mrs. Jackson had an extraordinary yield of honey about two years, and I wish that she would tell us about it.

Mr. Jackson—I had one colony that did not swarm which filled 10 supers of 24 sections each. The total yield from 18 colonies, spring count, was 2700 pounds and an increase of 19 colonies. There were no other bees near me. There was a heavy flow of honey all the season, and the bees were in the best of condition.

Mr. Kaufman—During a basswood flow I had a colony bring in as high as 22 $\frac{1}{2}$ pounds of honey in one day.

Mr. Kirkpatrick—I used to keep bees in Ohio, but got heavier yields of honey here than I did there. Last year I got 95 pounds of raspberry honey per colony, and this year I got 104 pounds per colony. I always get ready for the raspberry flow.

Mr. Chapman—I always get a good honey-flow from raspberry bloom.

SECOND DAY. BUILDING UP COLONIES IN SPRING.

Mr. Berg—How shall we build up colonies in the spring?

Mr. Root—Tuck them up warm.

Mr. Berg—As I have studied it I must have chaff hives. I do not think that bees wintered in the cellar do as well as those wintered in chaff hives. Bees must be in warm quarters with lots of honey, and must have a queen not more than two years old. During warm spells in winter bees wintered in chaff-hives have a chance for a flight. They also begin to breed early in the spring.

Mr. Chapman—I have had experience with both single-walled and chaff-hives, and I always winter my bees in the cellar, and lose only about 1 percent. I queen every year. I use the common Langstroth 8-frame hive, and put empty cases under the one filled with brood, using the queen-excluder when I commence to tier up. Last season my 4-story colonies averaged over 100 pounds per colony. I allow each colony to rear its own queen, but as some of these are queenless sometimes I keep some colonies for rearing queens. I have had some experience with spring work, and have not lost many colonies from chilled brood. My honey is from raspberry, clover and basswood. I kill all queens at the beginning of the basswood flow, as I want young bees for wintering.

Mr. Hilton—Mr. Chapman must be very familiar with his honey-flow.

Mr. Chapman—I put all my light colonies in a row, and see that they have honey enough to last them until the honey-flow commences. I have very little swarming, and produce only extracted honey.

Mr. Berg—I should prefer to have the bees strong before fruit-bloom.

Mr. Hilton—I could not follow Mr. Chapman's plan for comb honey. One must know his location and know how to work his colonies. Mr. Chapman has two seasons for brood-rearing, one early in the spring and one in the fall. Those reared in the fall are the ones to be put into winter quarters. Bees can not winter on unripe honey, and every bee-keeper must know his location in order to succeed. What method would do for one locality would not do for another.

Mr. Berg—I would like to ask if Mr. Chapman has good queens.

Mr. Chapman—I find I have better queens than I can buy.

Mr. Root—Mr. Chapman could not rear new races of bees in this way, nor those extra-long-tongued queens.

Mr. Chapman—My bees are all Italians.

Mr. Hutchinson—I see no difference between rearing your queens and swarming. By his method Mr. Chapman makes up any loss.

Mr. Chapman—I keep watch of the drones and have only selected ones with which to breed, and permit only two colonies to rear drones.

BUILDING UP WEAK COLONIES.

Question—How can a weak colony be built up in the fall?

Mr. Hilton—We can not build up a weak colony.

Mr. Berg—I unite a weak colony with one that has a good queen, and sometimes unite three in this way.

Mr. Kirkpatrick—All colonies should be strong when put into winter quarters.

Mrs. Jackson—Could a weak colony be kept thru the winter by feeding a cake of sugar?

Mr. Hilton—The matter of increase can be overdone. You must have the best conditions in order to get the best results. Colonies must be strong in the fall if you want them strong in the spring. Bees can be fed during the winter in the cellar, with sugar-syrup, but you must be careful not to burn it when making it, and the best sugar must be used.

FOUL BROOD—CROSS-FERTILIZATION OF FRUITS.

Mr. Hastings, the representative from this district, had been requested to attend this meeting, and he made his appearance at this time. Mr. Rankin explained to him the effect of foul brood, and what other States were doing to stamp out this contagious disease. Mr. Voorhies was called upon to explain what the effect would be on the fruit-growing interests of the State if the bees were destroyed by foul brood.

Mr. Voorhies—I am a pioneer in this part of the State. When I first came here there were no honey-bees, nor even bumble-bees, here, and we could not raise melons, pumpkins, nor squashes without hand fertilization. I do not think all the fruit-growers realize the importance of cross-fertilization. I am more interested in fruit growing than in bee-keeping. I keep a dozen or more colonies more for the purpose of cross-fertilization than for the profit I get from the bees in the way of honey-production. When the apple-orchards in this section first began to blossom, altho the trees blossomed well the fruit did not set as it should, and at that time we had a few bumble-bees in this locality, but no honey-bees. I am convinced from the experience I have had that the reason why we did not get more and better fruit was because the work of the honey-bee on the blossoms was lacking. Fruit-growers nowadays do not plant Bartlett pears or Baldwin apples in large blocks, but in alternate rows with other varieties, and this is for the purpose of cross-fertilization. But we can not always depend upon the wind to do this, as the wind does not always blow. There is nothing that I have found in my experience that effects cross-fertilization so perfectly as the honey-bee. In the growing of small fruits we have had the same experience. We plant pistillate, staminate, or perfect-flowering strawberry-plants, in alternate rows, for this very purpose. Cross-fertilization will give the best results, and if we want No. 1 or fancy fruits, we must have it. The blossoms of the small fruits do not usually keep open as long as the tree fruits do. The flowers of the trees may last several days, the much depends upon the weather, and the fertilization of these flowers may be a question of only a few hours. If one has bees near by to do this work he can be sure of having his trees well set to fruit. I do not see how I could well get along without the bees; one can not realize how important they are in this matter, unless he has had some experience.

Mr. Hastings—I will do what I can for the interest of my constituents while at Lansing. I have no doubt that the interest of fruit-growers as well as the interests of bee-keepers will be looked after. You have my best wishes for both of them.

It was moved and carried that the committee draft a bill similar to the one they have in Wisconsin, and present it to the Legislature.

It was also moved and carried that the next annual meeting be held at Petoskey, the time of the meeting to be decided by the executive committee.

The Association then proceeded to the election of officers for the ensuing year, which resulted as follows: President, George H. Hilton; vice-president, Elias Coveyou; secretary, Wm. G. Voorhies, South Frankfort, Mich.; treasurer, W. Z. Hutchinson.

Mr. Hutchinson then described queen-rearing as carried on by W. H. Pridgen, of North Carolina.

QUESTION-BOX.

Question—Does it pay to paint the bottom-boards?

Mr. Hilton—It pays to paint both sides of the bottom-boards.

Mr. Kitson—What kind of stands are best for hives?

Mr. Hilton—I would have 2x4 scantlings in clay, and have one inch ventilation.

Question—Which way should the hives face?

Mr. Hilton—I want my hives to face the east.

Mr. Hutchinson—I have tried all ways, and do not think it makes any difference.

Question—Should hives be shaded in summer?

Mr. Hilton—Hives do not need shade except in the hottest weather—in July and August. The shade-boards should project over the sides of the hives to shade it properly, and weights should be used to keep them from blowing off. Hives

should not be shaded in the spring, as the sun is best then to warm the hives.

Question—What size of hives is best?

Mr. Hilton—The majority prefer the 8-frame Langstroth. Comb honey can be produced with an 8-frame hive, but the 8 frames should be full of brood. To do this the honey at the side of the brood chamber should be extracted, and the empty frames put into the center of the brood-chamber. It should contain no honey, whatever. When there is a honey-flow be sure that the outside frames are full of brood; if they should be full of white honey, this can be uncapped and placed in the center of the brood-chamber, when the bees will carry it up into the sections.

Mr. Berg—I have used both 8 and 10 frame hives, and find that I get more filled sections from the 10-frame. I have had the 10 frames full of brood. I use chaff hives, mostly.

Mr. Beecham—I am in favor of one-half story hives, so as to keep the different kinds of honey together.

Mr. Hutchinson—There is no loss in deep uncapping of honey in the frames, as the bees will make more wax that would otherwise be wasted.

Mr. Rankin—I have experimented with the refuse of wax-extractors, and would like to get some samples to determine the amount of wax wasted in the different ways of extracting.

Mr. Beecham—The use of an iron kettle makes the wax dark; galvanized iron makes the wax green.

Question—Which is the better foundation—heavy or light?

Mr. Rankin—I have used 9 sheets to the pound, and also 13 sheets to the pound. I like the thin foundation better.

Mr. Berg—I want a thick top-bar for extracting frames, so they won't sag.

Mr. Hilton—Have every frame waxed before putting in the foundation.

Mr. Coveyou explained the merits of his double-walled super, with the confined air.

On motion the meeting adjourned.

WM. C. VOORHIES, Sec.

Instruments Used for Uncapping Honey.

BY FRIEDEMANN GREINER.

THE first new thing in the line of apianian implements coming to us in this new century will be an uncapping-machine—at least so it is hinted at. And, indeed, if a machine can be constructed to accomplish the work of uncapping for the extractor satisfactorily and speedily, we will have made a great step in advance, and all extracted-honey men will be quick, I think, to avail themselves of the new invention. How great this step in advance is, will be apparent when I show the readers what the implements are like that have been used for the purpose in the past.

Nothing better seems to have been found by the American bee-keepers than the honey-knife. [Fig. I.] Regard-

Fig. 1—Bingham Honey-Knife.

less of what the bee-keepers of other nationalities have used, and may be using, the knife is preferred by us in America. Numerous different instruments have been employed in the years gone by among the German bee-keepers. It would be difficult to state just how long the uncapping fork has been known, perhaps not less than 20 years. The long tines of the implement are pushed under the cappings and the latter are lifted off; sometimes they come off perfectly dry—no honey adhering. The work goes on rather slowly. I can do much more with the right kind of knife. The handle-part of the fork is usually made of metal. [See Fig. IV.]

To uncup honey for the bees I, like Dr. Miller and others, have used an uncapping-comb or harrow. This implement was originally devised by L. Huber, of Baden, Germany, in 1884, as shown in Figs. II and III. The tines

and teeth of the harrow are crook at the ends and filed sharp; with them the cappings are sort of raked off, but can not be removed so perfectly but what a liberal portion of them will find their way into the honey and will have to be strained out or skinned off.

I have no doubt that Dr. Miller's uncapping-comb varies somewhat in its construction from this one as well as mine; but we do not use ours to uncap for the extractor.

Another very old uncapping instrument is the spiked uncapping-roller. It works easily and rapidly, and it suits me to a dot. Of course it only mashes or destroys the cap-

[Fig. V.], with suitable small pieces of wood riveted on to make the handle complete.

Another uncapping instrument I see described as the uncapping-plane; but neither the illustration nor description is sufficient to give a clear idea of it, and as I do not find it spoken of in the bee-periodicals I judge that it is not a complete success.

The bee-keeping world is now awaiting with anxiety the forthcoming of Arthur Miller's uncapping machine.

Working According to Locality—Killing the Queens Each Summer.

BY S. D. CHAPMAN.

SITUATED as we are, just half way between the equator and north pole, we have here in the northern part of the lower peninsula of Michigan long, cold winters, and usually it is late in the spring before we get warm weather. We have deep snow, yet the ground never freezes in the woods, and very little in the fields. The snow comes early in the fall, and it is nearly the last of April before it disappears in the forests. Several seasons my bees have gathered their first pollen from elm and soft-maple while there was yet a foot of old snow in the woods. A mile and a half east of me we are nearly on the height of the land, and two miles west we are nearly on a level with the lakes. In the winter it is from seven to ten degrees colder on the higher land. Near the lakes we will find, usually, about one foot of snow; ten miles due east of there we will find four feet on the level. Raspberry and basswood come in bloom one week earlier on the low land. That part of the Grand Traverse region bordering on the lake and bays is not as frosty as southern Michigan or northern Indiana; but, just in my bee-range, we have early frosts, and the nights become cool early in the season. For this reason I believe in putting my bees in winter quarters quite early in the season—about October 15th. Years ago I found that my bees, if left on the summer-stands during our cold and frosty nights, would consume more honey from October 15th to the middle of November, than they would if put in the cellar October 15th and left till April 25th. I find from 8 to 9 pounds of honey will carry a colony of bees 190 days in my cellar. In the last 18 years, 180 days is the least time that my bees have been confined in the cellar—211 days the longest time.

At the present time I am using the ninth bee-cellar since starting with bees in this vicinity. I do not know as it is necessary for me to tell it, but I will say that in some of these cellars about all I had left in the spring was the cellar. The cellar that I now use is under my kitchen. It is 16x24, and there about 200 colonies in it. Some seasons there are a few more; in others, less. It is perfectly dry—so dry that you can not, at any time during the winter, find a drop of moisture the size of a pinhead on the under side of the cover that is right over the cluster of bees. I use no quilts nor cushions at any time of the year; and I prefer this kind of a cellar. I can not winter bees in a cold, damp cellar; but in a warm, damp cellar I have had them come thru seemingly in fair condition. They consume rather more honey, however, and they have not the vitality a colony has wintered in a warm and perfectly dry cellar. If I could hold the temperature of my cellar the latter part of spring to about 45 degrees, I have no reason to doubt that my bees would be in good condition, and not show a sign of disease at the end of eight months of confinement.

I use the eight-frame Langstroth hive. I have had some experience with very large hives, but in our cold climate we can not build up a colony in a large hive so that it can take advantage of the flow from raspberry. With us it is necessary that our bees are confined in just as small a space as possible, with plenty of stores, and just room enough for their present needs. This applies from the time of taking the bees out of the cellar, till the time sugar-maple and fruit-trees come into bloom. From the 5th to the 10th of May, we usually get our first honey from this source. In this vicinity there are a number of quite large bee-keepers, and every one of them has come to the eight-frame hive. We all work for extracted honey. With my method of management, the eight-frame hive is large enough for the need of any colony of bees I ever saw. And I know my colonies are as populous as it is possible to get with any style or size of hive.

I pay very little attention to my bees early in the

I. Spiked Uncapping Roller. II. Uncapping Comb or Harrow.
III. Single Tooth Harrow. IV. Uncapping Fork.

pings and does not remove them, so they find their way into the honey, even to a greater extent than was the case with the harrow when the tool is used to fit the combs for the extractor as some Germans do. In operating it they run it over the combs several times and in various directions. It would afford me little satisfaction to use the roller in this fashion, but when I have sealed combs I wish to have emptied by the bees, then the roller comes in play and has no equal. It has come to stay with me. I have made the roller part three inches long and about one inch in diameter; in rows lengthwise of the roller 18-inch wire nails are partly driven in, then the heads pinch off with nippers so as to have them protrude 1/8 inch or a trifle more. This little roller is hung in a simple frame made of 3/4-inch hoop-iron as shown in the accompanying drawing

spring. As I take them from the cellar, any colonies that seem light in stores are put in a row by themselves, and fed; but I do not break the sealed covers on the others till near the time of fruit-bloom. I find that all the time spent in trying to build up very light colonies in the spring is thrown away. If they make a live of it they can be handled to advantage later in the season. With us, the time to build up our colonies so that they are strong in the spring, is during the month of August.

At the beginning of fruit-bloom I examine all of my colonies. From all that need more room, those that have brood in six or seven frames, and as many spaces well-filled with bees, I take one frame of brood from the brood-nest, selecting the one containing the oldest brood. I shake the bees off in front of the hive, and put a frame containing all worker-comb in the middle of the brood-nest in place of the frame of brood I have taken out. I now put on queen-excluding honey-boards, and leave them on till the close of the season. The reason I take this frame of brood from the brood-nest is that I find the queens will lay much faster in the middle of the brood-nest than they will in the outside combs. This being the case, right in the middle of the brood-nest is where we want our queens to do their work. We are after all the young bees we can get.

Now I will tell you why an eight-frame hive is far the best in building up colonies early in the spring. It is far better to have the brood in six or seven frames in the eight-frame hive than to have the same amount in four frames in a large hive.

The frame of brood that I remove, is put in an extracting-super directly over the brood-nest, and the super filled on each side with empty combs. The bees go right to work in this upper story. If the weather is warm, and a little honey is coming in, I can, in four or five days, take from this same colony another frame of brood. If it is a strong colony I take two. They are put in the extracting super beside the first comb of brood. I take out one or two combs, as I need, that were beside the first frame of brood put in the super, and as the bees have cleaned these combs and put a little new honey in them, they are just right to put in the brood-nest in place of the brood removed. The queen will occupy such combs right away. We must be a little careful not to take too much brood early in the season from the brood-nest, or we may discourage the queen. While our object is to stimulate the queen to lay to her fullest capacity, I sometimes think our best bee-keepers do not know just what a queen is able to do, provided the conditions of her colony are just right—and we keep them so for 30 days.

In a short time I take more brood from the brood-nest. This time I put it in another super and set it under the first, or over the brood-nest. At this time I destroy the queen-cells that have been started in the first upper story. The bees will not swarm if a dozen queens hatch in the upper stories, but when I extract I shake the bees from these upper stories in front of the hive, and, if there is a young queen with them she will crawl in the hive and destroy the old queen, and I lose the use of a laying queen for eight or ten days just at the time I need her most.

I follow this system of management just as long as the bees will be worth anything to me on the raspberry or basswood. We must recollect that there is a certain time during the life of a colony, each season, when we can build it up faster than at any other time during that season. I expect to find not less than 13, and in some of my best colonies as many as 25, frames containing brood and honey—there is more or less brood in all of them. I think my colonies are 40 percent better than they would have been if I had given the queen the two lower stories and let them build up without any of my assistance.

Two years ago I set apart five colonies that were better than the average of the yard, and I gave the queen of each the lower stories, and let them build up just as suited their notion; adding upper stories and extracting as they needed. With the remainder of the yard (77 colonies) I used my method of management. At the end of the season I had 1400 pounds of honey, extra, to my credit from the 77 colonies. This is about 23 pounds per colony; and I sold this honey at 6¢ cents on board the cars. I tried this experiment in an out-yard, three miles from home. It took one-half day to go to this yard, put brood in the upper stories, destroy the queen-cells, and return home. I did this eight times, requiring four days of time, and I had this 1500 pounds of honey to pay me for my four days' labor. The showing in favor of the 77 colonies would have been much better if there had not been a number

that did not amount to much on the raspberry. This is not all; my bees *never think of swarming*. I am complete master of the situation, under any and all conditions. This alone is worth the four days' time.

During the last three years, raspberry has yielded about the same each season. My best colonies, those occupying four stories, have yielded, each season, from 160 pounds to 200 pounds per colony. My three-story hives during this same time have averaged 90 pounds each; my two-story hives from 20 to 40 pounds.

The wild red raspberry comes into bloom not far from the 5th of June, and it yields continually till near the 1st of August; to it is on the decline after July 15th. The past season it came into bloom the *second time*, and my bees gathered fully five pounds per colony from the 1st to the 10th of October. This is nothing unusual, tho I do not recollect getting so much honey so late in the season from this source. After my bees were in the cellar there was bloom, green and ripe berries, up to November 1st.

Basswood comes in bloom about the 15th of July; but we have had little honey from this source the last four years. When basswood yields, it is not those extra-large colonies that wintered the best, that built up early in the season and gave us such large yields from the raspberry, that prove to be the best on the basswood. Far from it. Those large colonies built up rapidly in the spring, but it is impossible to keep our queens laying at their best except for a short time. The honey may be coming in every day, the bees are getting old, and those colonies are on the decline, while colonies that were lighter early in the spring have been building up, and by the time basswood comes into bloom they are liable to send out a larger working force of bees that are just the right age to take advantage of the yield from basswood; that is why our lighter colonies prove the best on the basswood. If we are to make a success of any colony we must bring it thru the winter in *good condition*; then we must thoroughly understand our location; and a certain time before the honey harvest we must stimulate that colony to build up as rapidly as possible. Remember, the faster the colony builds up, the more vigorous are the bees; so that the colony is able to bring into action the largest possible force of bees that are just the right age to take advantage of the flow.

From about the 1st to the 10th of July I kill all of my queens. I have practiced this for 10 or 17 years. I would not go to this expense unless I thought I had some pretty good reasons for doing it, as it takes a day in each yard to hunt them up. Where queens are worked as I work them they never prove as good the second year. With my management the average life of the best of queens is not over two years. The first year of their lives, not one queen in a hundred is superseded. The second year, from 30 to 50 percent of them will be superseded in the fore part of the season, just at the time we want a good queen in every colony. This makes a big hole in my honey crop. At the time I kill my queens my colonies are in the very best condition. I am sure of just as good queens as we can get with the most favorable swarming conditions. After killing the queens, for about 25 days, no eggs are laid in the hives. Our colonies are not rearing a lot of bees that would be consumers for this length of time. As the brood hatches in the brood-nest the bees fill these combs with honey, leaving the colony in better condition for winter. One of my best reasons for killing the queens is that thereby each colony is furnished with a good young queen to build them up for winter.

Experience and a careful study of this matter will show many more reasons why it is profitable to kill the queens each year in northern Michigan. As I said in the beginning of this article, the time to build up colonies so they are strong in the spring is during the month of August. I use the same method in the fall that I do in the spring, but not on so large a scale. Near the first of June I select from four to six of my best colonies, and in each colony I put two frames containing largely drone-comb, for the purpose of rearing drones. I do not intend to rear any drones except from these colonies, as I use only worker-comb in the brood-nests, and if a few drones are hatch they must nearly all hatch in the upper stories, where they soon worry themselves to death or are killed in trying to get thru the queen-excluder.

If I wish to run a colony or two for comb honey, 15 or 20 days before the end of the honey harvest I take one or two of these large colonies (they are twice as large as any colony that is run for comb honey from the beginning of the season) and remove the three extracting supers, and in their place I put three section-cases. They will fill three

about as soon as they will one. In 30 minutes these section-cases are filled with bees; and they go right to work. I can take more section honey, late as it is in the season, than I could if I had worked the colonies for section honey from the beginning of the honey harvest; and I have already taken 60 or 80 pounds of extracted honey before I put on the section-cases. They do the work so quickly that we get an extra, No. 1 quality of section honey.

I have told you that my bees do not swarm, and I think I can tell you *why* they do not swarm. The raising of the brood to the upper stories, distributing it in three or four places, there is no large body of brood in the brood-nest at any time; especially *sealed brood*. From the time I put up the first frame of brood they have been starting queen-cells in the upper stories, and every 10 or 12 days I destroyed them, but during all this time (four to six weeks) they have not attempted to start a queen-cell in the *brood-nest* where the queen is laying. Eleven years ago I used the same management as I do at present. That season I killed 140 queens, and over 80 of that number *did not start a queen-cell in the brood-nest*; and the brood was too old in the upper stories. I should have had over 80 queenless colonies had I not discovered it just in time to take cells from those colonies that were rearing queens.

I mention this case to show the conditions into which we can bring our colonies; and how slow they are sometimes even to recognize the loss of their queens.

I think these are the reasons why my bees do not swarm up to the time that the young queens hatch; and I think this management has something to do in keeping them from swarming at the time the queens hatch. My bees do not get the swarming-fever. When the young queens hatch, the conditions in the hive are changed; I have put no brood in the upper stories for a week or more previous to killing the queens. If there is a colony in the yard that has the *swarming-fever* at the time I killed the old queen, that one will swarm from the 11th to the 13th day, even tho I destroyed every sign of a cell at the time I killed the queen, while the others do not hatch a queen till the 14th or the 16th day from the time of destroying the queens.

At the time the queens hatch there is no brood in the upper stories, and I extract the honey closely, so, at this time, there is plenty of room. This is the reason they do not swarm at the time the queens hatch.

I have run my out-yard of 90 colonies the whole season, killed all the queens, and have had but one swarm; and that swarmed at the beginning of fruit-bloom before I had put on any upper stories. The swarming-fever is a spontaneous impulse, and we can so change the conditions of a colony that it is liable to contract the desire to swarm in *15 minutes*. Supposing, at the time the young queens hatch, each colony has a young queen, and most of them have destroyed the queen-cells, now remove all the upper stories, confining these large colonies to the brood-nest, and I should expect *every one of them to swarm*. I would have my hands full for a day or two. With these conditions I have known a colony to swarm in 30 minutes after we had brushed the bees carefully from the combs. If we shake the bees from the combs we cover them with honey, and have spoiled the experiment.

Just before the queens hatch I make my increase by division; and it is not at the *expense of my honey crop*. In union there is strength. I have kept the bees in each colony together till near the end of the honey harvest.

Many of our best writers have frequently told us always to keep our colonies strong. I hardly think this is good advice for our locality. Years ago I would have given a good deal if they had gone a little farther and told us just how they managed to *build up* their colonies so they were strong. And now, just for the fun of it, I would like to know, when their colonies are strong how they always keep them so.

It is necessary that every bee-keeper should understand his own locality, and what is best adapted to the requirements of his location.

I have not written this as a pattern for bee-keepers in New York, or California, or any other State, but simply at the request of a few bee-keepers living in northern Michigan, who wish to try my method of management.—Bee-Keepers' Review.

Antrim Co., Mich.

The American Fruit and Vegetable Journal is just what its name indicates. Tells all about growing fruits and vegetables. It is a fine monthly, at 50 cents a year. We can mail you a free sample copy of it, if you ask for it. We club it with the American Bee Journal—both for \$1.10.

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

A REVIEW OF "THE HOME CIRCLE."

And so it's a "Home Circle" our journal is to have. A poor one would be just so much space wasted. A good one, without much doubt, would decidedly help the paper to prosper. I can't say I exactly like that quivering editorial half-promise to steal all the space needed from the advertisements. Sounds as if the editor hadn't the "sand" to edit his own paper. (He has, tho.) Other things being equal, the bee-paper that makes itself of interest to the whole family will distance the one that only interests one individual. In the good old times, when to meet a bee-keeper was to meet a man consumed with a raging "bee-fever," the above dictum may not have been true, but you know we have to live in present times. The species of mosquito whose bites inoculate bee-fever has become nearly extinct. As for the old patients, they are mostly "pretty well, thank you," at 97 $\frac{3}{4}$ degrees Fah. And, don't you know, the prosperous paper (besides its side-issues) will have more acres in bee-reading, and more fertile acres, too, than the unprosperous one can possibly sport. However correct you may think his principles to be, the editor who allows his paper to "spring-dwindle" will make you but little return for your dollar. Cause why? *He can't*. It hardly needs saying that Prof. Cook is a man who has right ideas—progreed ideas—about what home ought to be.

From the concentrated wisdom of the seventeen Maxims I will quote just two words: "Avoid moods." Moods all right in grammar; and I think I'll advocate "high license" instead of "prohibition" for moods in folks. Don't believe I exactly want a friend whose whole life is one even thing, unvaried by a single change of mind. Constant, even-toned sounding of one note is hardly the thing—even if the note is "soul." And we'd greatly want to change off upon another mood, that fellow whose forever note is "Me," with a big M. License of \$10,000 for the Me-Indicative mood. Also the contemptuous Poh!—tentual mood, and the too-imperative. Imperative mood should be muted well for the public treasury. But the main idea of the maxim is right. Down on the home-circleist who won't give a civil answer to a civil question, and hides behind an excuse. Perchance this is an excuse: "I have an angelic mood which I wear much of the time—so you must remember that I average well—just for now this is my nearly-innocent and not-very-big Polar-bear mood." That individual should be compelled, somehow, to see self as others see. Pages 163, 170, 171.

IMPORTANT POINT IN SPRAYING TREES.

One thing in Mr. E. R. Root's excellent paper on spraying trees in bloom is less familiar to the mind of the bee public than the rest of the points made. The poison is charged with damaging the pollen. Grains will not develop when moistened with the solution, or even with a half-strength solution. Surely it looks hardly wise for the orchardist to depend for pollen on the flowers he fails to hit. Page 120.

BUYING SUPPLIES WITHOUT A GUARANTY.

When it gets to the point that retailers generally are not willing to buy supplies without a guaranty as to what things are really made of, then indeed a pure-food and pure-honey morning does begin to streak the east—or is it the west in this case that gets streaked first, and needs it most? We don't feel very malignant toward any one, but we trust the swindlers also feel a little streaked. Page 121.

WORMS ON TREES AND IN HIVES.

And now comes a man who apparently thinks the worms (so-called) he finds in his apples, and the familiar ones of the bee-hive, are the same thing. And he *discovers* (in certain frame of soul how we do discover things?) he discovers that each color of apple has a similarly-tinted worm—and ditto of the bee-hive that doth stand beneath that tree. Mr. Tesla would better be looking a little out for his laurels. But while we are contemplating this good friend we would better be seeing ourselves a little also, and *our* inventions and discoveries. I once discovered the source of the power which makes the earth revolve on its axis, and came near trying to publish it to the world. I made a machine that would generate axis

rotation beautifully, and I thought I knew why. I didn't, tho. Page 126.

THE WISCONSIN BEE-MULET.

That proposed legislative mulet of \$400 for moving an apiary is of interest as showing the crudity of some people's ideas of bees. Evidently think the bee-man is getting a fortune too fast, and that he ought to be made to "shell out" some of it. Page 131.

"AFEARED" OF A HONEY-TRUST.

And so, Mr. Aikin, a convention will wrestle, and wrangle, and suggest, and advise, and demand—and then suggest and advise the opposite thing—and then appoint a committee to sell the honey crop of a State—and provide for the greasing of the wheels—not one dollar! Still Mr. A. has hopes, I, too, have—what would he hopes in a different person—I'm "afeared" that the honey-trust will some time be an accomplished fact. Page 132.

ORTHODOX AND UNORTHODOX GOLDEN BEES.

According to Mr. Doolittle's interesting history of the five-banded there seems to be in the land both an orthodox and an unorthodox golden bee. Latter a mongered worthy of all sorts of perdition—but doubtless handy to bear away the sins of both kinds.—Still, whether you mongrelize, or whether you eschew mongrelization, this critic for one doesn't believe you can breed golden color to the front without at the same time breeding to the front the ancestral qualities of certain ancestral bees. Wonder which kind it was that a friend of mine presented me. They were beauties, indeed; and they also seemed good-mannered, and exceptionally enterprising; but they didn't *begin* to get thru the first winter alive. Page 134.

BEE-PARALYSIS AND QUEENS.

The article of O. O. Poppleton, on page 134, should not be lightly past by, even if it is a sort of insoluble puzzle. It looks a little as if the virus of paralysis has spread *invisibly* pretty much everywhere, but developing to due serious mischief only in favorable climates showing mainly in the inferiority and short-livedness of queens. And how about the resident Florida bees? Are they free from it (by the extinction of all not free), or are they immune to the virus which they carry as well as the rest?

SHELTER AND SHADE FOR BEES.

That mid-nod, rod-long umbrella of Mr. Wagner's, to shelter and shade his bees, it has obvious good points; and it is moreover somewhat of a novelty, in these last days when novelties are scarce. We tip our hats to it just at the angle shown in Fig. 2. Possibly some might say that the arrangement as a whole has obvious disadvantages also. Page 135.

UMBRELLAS BY MAIL.

'Umbrellas by mail, eh? If Uncle Sam should adopt the notion would any lost umbrellas, we wonder, imitate the "vildest sinner" and return? Still viler than the vildest sinner most of 'em, we fear. Possibly, our French and Swiss brethren, you have carried postal reform an inch or two too far already; but what say to an apiary by mail at 15 cents per hive? Then migratory honey-crabbing might get up-to-date. And the exhaustion of the subject he complains of seems to improve C. P. Dadant, page 135. Would almost like to see what kind of brick he would make when deprived of both straw and clay.

HOT AND COOL SUGAR-HONEY TALK.

Prof. Cook's hot words about sugar-honey on page 149—possibly it might be well to say some words in addition which are a little cooler. Whether sugar syrup manipulated by bees is "honey" or not, is, to a certain extent a matter of definition of words, and of opinion. Now people may be atrociously wrong in their definitions and opinions without *entirely* falling into untruth. World is full of just such people; and let us try to be patient with them. Again, some of those whose—not quite falsehoods—we deplore may never have tasted the real article, stored when bees were in the active condition. Wake the bees up after they have ceased work for the season, and make them carry down in haste some syrup, and *occasional samples* of this kind of work may possibly taste more like syrup than they do like honey. But the real article, if I am right, not only has a honey-like taste in a general way, but it has a decided special taste, not at all suggestive of sugar, that would almost deceive the very elect into calling it the flavor of some particular kind of flower. Exactly that happened to Mr. Heddon on a certain rather public occasion. Again (to resume) our senses of smell and taste, rather more

than the other senses, are often be-tricked, especially if our minds are excited. For instance, I abominate tomatoes. Once my mother gave me a piece of very sweet pie. It tasted good. Later on I found out it was made of preserved tomatoes—and then it tasted bad—couldn't eat such stuff to save me, then. It is related that some express clerks somewhere out West buried a box of pumps, that chanced to be shaped like a coffin, because the corpse inside *smelt so bad*. It was not falsehood that allied these clerks, but just the fallibility of the poor human critter.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Brood Diseases.

A subscriber sends me a sample of brood that may be affected by foul brood or something closely allied to it. In matters of so much importance it is wise to take no chances and to waste no time; so I advise any one who has reason to think that anything like foul brood, pickled brood, or black brood, is present in any of his colonies, to send a sample with the regular fee of \$2.00 to Dr. Wm. R. Howard, Fort Worth, Tex., so that it may be analyzed, and then the sender will know positively what is the trouble, and what is to be done with it. I know of no one in this line more competent than Dr. Howard, and bee-keepers owe him a debt of gratitude for his investigations. C. C. MILLER.

Transferring and Dividing Colonies.

1. My bee-book tells how to transfer colonies, but if I do it by the Heddon plan, what is to hinder the parent colony from being robbed during the 21 days, if near the apiary?
2. Why could I not drum them into the new hive at once that has old combs, having it tight around the bottom, not using the forcing-box?
3. If I make swarms by dividing according to the textbooks, will the queenless part rear a queen if there are no queen-cells at the time of dividing? Why wouldn't they be worthless, like many other queenless colonies?
4. Would colonies made by dividing, be likely to produce as much surplus honey as if left to swarm naturally?

MASSACHUSETTS.

- ANSWERS—1. The supposition is that the bees will defend themselves against robber-bees, but it will be well to help them by contracting the entrance somewhat.
2. That certainly will be better, if the hives are such as to allow it.
3. Set it down as a fact that if you want good queens they must be in strong colonies and in favorable circumstances at least till sealed. That settles the question that the queenless part must not be allowed to rear a queen from the start unless strong and gathering.
4. Just as much, if of the same strength and having the same advantages.

Spring Requeening—Introducing Method.

If you were to requeen an apiary in the spring with young queens from the South, what method of introduction would you practice? IOWA.

ANSWER—This matter of queen-introduction is such a constantly changing and elusive thing that it is hard to tell a month ahead what one would do. Just as it happens to look at this minute, I suppose I should take the regulation way of introducing in the cages that brought them. If I didn't follow that exactly, it would be to do something that had before proved successful in my hands, without much reference to what had succeeded with others. Explain it as we may, there's something about the matter that allows A to be successful in one way and B in another, while both

might fail if they should swap plans. If time was plenty, and it was decided to take extra precaution, this might be done: At the time of day when bees were busy flying, remove the old queen and set the hive in a new place, after first taking from it a frame of brood and bees to put in another hive on the old stand; put the new queen in the removed hive and perhaps two days later return to the old place, giving it back its frame of brood.

Now it's none of my business, but if you're requeening with young queens to avoid swarming, I'll volunteer the remark that in this locality it doesn't do to make the change too early.

Transferring—Controlling Swarming.

I got a start in bees last summer. Can I transfer or increase, and incidentally control swarming, by placing Langstroth hives with starters *under* or *over* box-hives? or does the "A B C of Bee-Culture" (which I have) cover the whole ground? If so, I shall have to follow instructions therein.

INDIANA.

ANSWER.—If you put a box-hive over a frame-hive having its frames filled with foundation, and allow the bees to work down and fill the lower hive, you will probably have, if you wait long enough, all the brood in the lower story, and consequently the colony transferred, and you may confidently count on no swarming. With a little more trouble you can have a surer and quicker way. Put on the stand of the box-hive a movable-frame hive filled with foundation, and put over it a queen-excluder. Drum the bees out of the box-hive until you think you have the queen, and run them

into the frame-hive. Set the box-hive over the excluder, and close up any opening over the frame-hive or under the box-hive. A week later look to see if you have eggs below, and if not drum again. Three weeks after the queen is drummed out all the brood will be below (unless it be a small amount of worthless drone-brood), and the box-hive may be disposed of. No danger of swarming. It will be a help in either case if you can get a frame of brood from another colony and put it in the frame-hive at the first.

Stimulative Brood-Rearing in the Spring.

When should I begin, and how much should I feed, to stimulate brood-rearing in the spring? The colonies are pretty weak.

ILLINOIS.

ANSWER.—Unless you are somewhat experienced, and unless you are very careful, you will do well to let stimulative feeding alone. It may do good and it may do harm. If you feed so as to start the bees to flying out when it is so cold that they will be chilled and lost, it will be a losing speculation. If the bees are started out flying, and then it suddenly turns cloudy when the temperature is not very high, the bees may never return to their hives. It may be a safer thing, and perhaps just as well in the long run, if you see that the bees have abundance of stores, and have all cracks about the hive closed, and then leave them to themselves. But if you think it best to try stimulative feeding, begin when the bees fly out every day at least a little, feeding every *evening*, or every alternate evening, a half pound of sugar with an equal or greater quantity of water.

It Stands to Reason

That There Is Money Saved in Buying Direct from the Manufacturer.

The profits between the manufacturer and consumer are large. **We Save You These Profits.** We are the largest manufacturers of Vehicles and Harness in the world selling to the consumer exclusively. For 28 years we have conducted business on this plan. We guarantee to give you much better quality for the same money, or the same quality for less money than the dealer, jobber or supply agent.

We Ship Anywhere for Examination and Comparison, Guaranteeing Safe Delivery. We have No Agents.

We make 178 styles of vehicles and 65 styles of harness. Our Large Catalog shows every Vehicle and Harness we make and gives prices. **IT'S FREE!**

DESKS FOR GENTLEMEN AND LADIES!

Combined Desk and Book-Case

Size, 66-in. high, 36 in. wide,
19 in. deep.
Price, \$13.75.

THESE DESKS are made of quarter-sawed oak, first-class finish, well put together, and will please every purchaser. They are an ornament to any home, as well as being a useful necessity. Would make a FINE GIFT for father, mother or sister.

The Combination Desk and Book-Case

is just the thing for a farmer or business man of any kind, to keep his private papers in, and for his books, etc. The drawers have locks, and there are a number of pigeon-holes inside each of the desks shown herewith.

The low prices quoted are f.o.b. Chicago. Send for free catalog. Address,

The Royal Star Combination
Game-Board Co.,

773 to 779 Carroll Ave., CHICAGO, ILL.

Ladies' Desk.

Size, 40 in. high, 25 in. wide, 15 1/2 in. deep.
Price, \$2.85.

[The above firm is entirely reliable.—EDITOR.]

You'll be surprised at my bargain offers. Send post for catalogue today. It is FREE. Tell your friends to send too.

F. B. MILLS, Box 88, Roschelle, Oremburg Co., N. Y.

GENERAL ITEMS

Good Yields of Honey—Foul Brood.

I have been in the bee-business about 10 years, commencing with one colony. I aim to keep between 50 and 60 colonies all the time now. In 1899 I secured 6,000 pounds of extracted honey, and last season I secured 4,000 pounds. I sell it all at Boulder and the mining towns in this vicinity, getting from 8 to 10 cents per pound for it. I put it in two-pound Mason jars, and also in the cans, and have a ready sale for it. Our honey is mostly gathered from alfalfa bloom.

Foul brood got into my apiary last season, and as I had never had any experience with the disease, I lost the use of a good many colonies by transferring them too late, but I saved the most of the bees, and what honey I got was fine.

F. W. BAKER.

Boulder Co., Colo., March 15.

Bees Wintered All Right.

My bees are now at work on peach, plum, mustard and turnip blooms, and have come thru the winter all right, and with no loss. I had bees swarm last April, and I believe they will swarm again this year in April.

R. P. DAVIES, M. D.

Lamar Co., Tex., March 23.

National Bee-Keepers' Association.

The report of the Chicago convention was particularly valuable and interesting. I believe it should be issued in pamphlet form, thus making the fund of information contained therein easily accessible. I am more impressed with the value of the National Association and its possibilities in the interest of bee-keepers every time I think of it. With united action and support of the fraternity it seems to me that the Association could be made the distributing agent for the product, and the manufacturer and distributor of supplies as well as bee-keepers' trust and why not? With concentration in production and

distribution, the expenses of both would be minimized, and the large slice now taken by the supply trust before, and the commission trust after, the crop is secured, would largely revert to the producer.

That this is not all guesswork I am convinced from late experience. In 1900 I askt for prices from a firm that advertised "Root's goods at Root's prices," on 1,000 broad-frames, sending them sample. They quoted \$21; I got the frames made for \$12.50. This is no reflection on the firm, as the prices of other supply dealers vary but little from the above. The margin saved in this transaction shows what may be done if we wake up and do it.

My 70 colonies are all alive and well, but have had no chance for a general flight since last November. WM. WRAY.

Gration Co., Mich., March 6.

Outdoor-Wintered Bees.

I am afraid that some of our outdoor-wintered bees have been confined too long for their own good. Bees in the cellar never were quieter at this time of the year.

FRIEDHEIM GREINER.

Ontario Co., N. Y., March 18.

Bees Did Fairly Well.

My bees did fairly well last season. I secured 2,600 pounds of comb honey from 37 colonies, which I sold for \$280 10.

W. G. LINDZA.

Boulder Co., Colo., March 19.

Bees Wintered Splendidly—Prospects Bright.

My bees have wintered in fine condition, 90 colonies having come thru without a single loss. I hear some of my neighbors complaining of losses, but I attribute it to negligence on their part.

We have had an unusual amount of snow this winter, which insures plenty of water for irrigating purposes, hence a large crop of alfalfa, and the bee-keepers are expecting large returns—disappointments not included.

The weekly contents of the "Old Reliable" are as eagerly awaited as of yore.

JERRY W. LYLE.

Washoe Co., Nev., March 18.

Bees Wintering All Right—Bee-Literature.

We are having a fine winter, and bees seem to be wintering all right so far. They gathered the first pollen on Feb. 17th, and again on March 2d and 3d, but the weather has turned cold again, and they have stop work. I am employed in a store here, and see a great many people, and have the opportunity

Harry N. Hammond Seed Co.—We are very glad to call the attention of our readers to the Harry N. Hammond Seed Co., of Bay City, Mich., who have been advertising in these columns for some time past. Very many of our readers will remember when Harry N. Hammond started growing and selling seeds in a comparatively small way at Friesland, Wis. This, however, was probably have crissit out the ambition of most business men, but with commendable pluck and enterprise Mr. Hammond decided to re-establish his business on a larger and more substantial basis than ever. Realizing that it would be an advantage to have his warehouses and shipping business in a larger city, he incorporated his company and located at Bay City, where large and commodious buildings were erected for his use. These people issue a very complete catalog which we will be glad to have our readers write for if they have not already done so. In writing please mention the American Bee Journal.

Marshfield Manufacturing Company.

QUEENS!

Improved Golden and Leather-colored Italians are what **H. G. QUIRIN** rears.

We have one of Root's best long-tongued Red-Clover Breeders for their \$200 queen, and a Golden Breeder from Doolittle who says if there is a **BREEDER** of golden bees in the U. S. worth \$100, this one is worth that sum. The above breeders have been added to our already improved strain of queens for the coming season.

J. L. Gandy, of Humboldt, Neb., wrote as on Aug. 5th, 1960, saying that the colony having one of our queens had already stored over 400 pounds of honey. Most's colony, he states that he is certain that our bees work on Red Clover, as they were the only kind in his locality and apiary.

A. I. Root's folks say that our queens are extra fine, while the editor of the American Bee Journal tells us that he has good reports from our queens from time to time. We have plenty of offers of unsolicited testimonials.

After considering the above evidence, need you wonder why our orders have increased each year? Give us a trial order and be pleased. We have years of experience in mating and rearing queens. Safe delivery will be guaranteed, and instructions for introducing sent with each lot of queens.

QUEENS NOW READY TO MAIL.

Warranted stock, \$1.00 each; six for \$5.00
Tested queens, \$1.50 each; six for \$8.00
Selected tested, \$2.00 each; six for \$10.00

We have 100,000 Folding Cartons on hand, and so long as they last we will sell at \$4.00 per 1,000, with four address printed on it two colors; 50¢, for \$2.75. At above price you can not afford to place comb honey on the market without carrying it. Address all orders to

to talk to a number of bee-keepers, and I always speak a good word for the "Old Reliable," but it seems to be hard to induce some of them to take a good bee-paper, and thereby inform themselves along the line of bee-culture. I have taken the American Bee Journal for about nine years, and I don't see how I could keep bees without it.

A. J. FREEMAN,
Neosho Co., Kans., March 5.

Rendering Beeswax.

With reference to the color of wax I would like to say a few words in regard to my experience with the way that I have melted during the past five or six years. It is true that there are two kinds of wax, and that both may be produced in the same apiary, but I believe the foreign particles have a good deal to do with the color of wax, just as they would have with hot water or hot lead, giving them a dull, dirty appearance that no amount of slow cooling will brighten. The secret of bright wax does not lie in the slow cooling, but in the melting, which should be very slow. Extract the wax in a solar extractor, then put it in an earthen pot, and set the pot in a dish-pan full of cold water, setting it on the stove and allowing it to come to a point where the wax begins to melt. Then I push it back and let it melt as slowly as it will, and that is about 20 pounds a day. As fast as it melts I dip it off and put it into molds, which I have sitting in hot water. This allows slow cooling so that the dirt may settle. I will let it in small cakes weighing about two ounces each for 7 cents a cake.

My bees are wintering well.
ROBERT J. CARV.
Fairfield Co., Conn., Feb. 25.

Belgian Hares and Bees.

Prof. Cook was right in saying that Belgian hares were all right to combine with the bee-business, as few animals can be found that will yield more profit than Belgian hares. This can not be said of bees in this locality, as we have had nothing but short crops and failures for over 10 years, which has made it necessary for me to add something else to bee-keeping.

Last season was one of the poorest we have ever had. I did not get a pound of surplus honey and have had sugar-syrup in order to keep the queen-rearing colonies in good condition for rearing queens.

After purchasing the Belgian hares the first and most important thing is to have a place for them that is dry and well ventilated, as they can not stand dampness, but can endure almost any amount of cold if they are dry and not exposed to a draft.

They are reared in a small room called a hutch, about 24x32 feet, or larger if convenient. Place a nest in one end of it, 12x21

PAN AMERICAN EXPOSITION.

Nothing since the World's Fair, at Chicago, in 1893, has elicited the widespread interest that is manifest, all over the world, in the Pan-American Exposition, which is to be held in Buffalo, from May 1 to Nov. 1, 1901.

The purpose of the Exposition is to illustrate the progress of the countries of the Western Hemisphere during a century of wonderful achievements, and to bring together into closer relationship the people composing the many States, Territories and Countries of the three Americas. Acting under proper authority, the President of the United States has invited all the Republics and Colonies of the American Hemisphere to join in commemorating the close of the Nineteenth and beginning of the Twentieth Century, by holding this International Exposition on the Niagara Frontier.

For this important event, the Nickel Plate Road has issued an attractive, descriptive folder-pamphlet, elaborately illustrating the Pan-American Exposition, the buildings and grounds.

The Nickel Plate Road is the short line between Chicago and Buffalo, and affords competent train service from Chicago to Buffalo, New York City, Boston, and all points East, with trains of modern equipment, on which no extra fares are charged; also dining-car service of the highest order. It affords meals in its dining-cars on the individual club plan, ranging in price from 35 cents to \$1.00.

Call on any ticket agent for Pan-American folder of the Nickel Plate Road, or address John Y. Calahan, General Agent, 111 Adams St., Chicago.

Parties desiring hotel or rooming accommodations at Buffalo or Niagara Falls, during any period of the Pan-American Exposition, are invited to apply by letter or otherwise to F. J. Moore, General Agent, 291 Main St., Buffalo, N. Y. No. 4-12A3t

feet. Here the doe will make her nest from soft litter that should be given her about two weeks before she kindles. She will make a hole in this litter, and line and cover it with her own fur. She nurses her young late only at night and early in the morning, and if she ever lies with them I have not seen her.

The feeding is also an important point. The standard feed for them is alfalfa or clover hay with oats, bran or chaff. She will eat withers should be given extra care and feed, especially if the litters are large, and they quite frequently number 11 and 12. Bread and milk is easily digested, and is good food for the youngsters from the time they are born to the 10th or 20th day thereafter. Feed should be furnished to all nursing does, as neglect at this time would interfere with the milk supply, and cause the loss of the litter. We usually keep feed before them all the time, so that they may eat when they feel inclined to do so.

The meat of the Belgian hare is very good, and as they breed the year around we have a supply of choice fresh meat every day in the year.

The Belgian hares make nice pets if treated kindly, and especially delight the children.

Page Co., Iowa, March 7. J. L. STRINGER.

Quality and Price.—One of the first things the successful business farmer learns is that it does not pay to buy cheap and shoddy goods—cheap and nasty. Some one has called them. We believe that this is especially true of vehicles. It takes good material to make a good carriage or buggy, and good material costs money. It's the same way with the work that goes into it; it cannot be built for nothing. So when we see a vehicle advertised at an extremely low price we are apt to think that it is dear at any price, and so it is, for a shoddy vehicle, besides never looking well, costs more than a good one for repairs, to say nothing of the danger of breaking your neck every time you get into it. But, on the other hand, a man need not pay a fancy price to get a really good job, especially when he can buy a first-class vehicle from the maker direct. Take the famous Split Hickory Vehicles, for example. Now that the manufacturers of these well-known goods have decided to discard jobbers and dealers and sell direct to customers, you can buy a vehicle which you know is right all the way thru, a vehicle with a title that will bring it all the way to you on approval, for one-third less than dealers ask. There is not a better line of vehicles in the world than the "Split Hickory's." Not only are they substantially made, but they have a style and finish appearance found in few makes, and a dozen little conveniences covered by patents, which make them the leaders wherever introduced.

The new catalog, showing Split Hickory styles, is a most valuable book on vehicles, containing many things every owner of a carriage should know, whether he buys a new one, or not. A copy will be sent to any interested reader who addresses the Ohio Carriage Co., 6 West Broad St., Columbus, Ohio. Please mention the American Bee Journal when writing.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, March 20.—The choice grades of white comb honey sell at 10 cents, with supply about equal to the demand; all other grades are slow of sale at the present time. Fair grades of white, 14c; best amber, 13c; 12c; mixt colors, 10c; buckwheat, 9c. Extracted, white, ranges from 7c to 8c; amber, 6c to 7c; buckwheat, 5c to 6c. All of the extracted is governed by quality and favor in the range of prices, the lowest figures in either of the colors applies to the sour, or off-flavored, and unripened. Beechwood, 10c.

R. A. BURNETT & Co.

NEW YORK, March 19.—Our market is virtually bare of comb honey, and there is a fair demand for all grades. Fancy white is still selling readily at from 15c to 16c; No. 1 white at from 13c to 14c; other grades at 11c to 12c. Buckwheat, 11c, according to quality and style of package. As to extracted, the market is quiet and inactive, and a certain amount will have to be carried over again. Prices are declining somewhat, and it is honey is in demand for large lots, concessions will have to be made. We quote: California white, 7c to 7½c; light amber, 6½c to 7c; other grades at 5c to 6c. Southern, 5c to 7c per gallon. Beeswax very firm at 28c to 29c, and for exceptionally fine yellow, 2c.

HILDRETH & SEGELKEN.

BUFFALO, March 21.—Much better demand for fancy comb at 15c to 16c; extras, 17c; common, dark, etc., at 10c to 11c. Extracted, 6c to 8c, and never in much demand. Bateson & Co.

OMAHA, March 30.—Demand fair; stocks light. Fancy white comb, 15c to 16c. Extracted moving slowly at 7c to 8c. White. We do not look for any particular change for the balance of the season, as present supply will just about be sufficient to supply the trade until next crop gets into market. PEYKE & CO.

DETROIT, March 21.—Fancy white comb, 14c to 15c; No. 1, 13c to 14c; dark and amber, 10c to 12c. Extracted, white, 6c to 7c; amber and dark, 5c to 6c. Beeswax, 27c to 28c. M. H. HUNT & SON.

CINCINNATI, March 21.—The demand for comb honey is nearly over, the stock of it will be cleaned up. Demand for extracted is still good. Extracted is in fair demand; dark sells for 5c; better grades bring 6c to 7c; fancy white clover from 8c to 9c. C. H. W. WEBER.

KANSAS CITY, March 23.—Receipts light; demand normal at steady prices. Fancy white comb, 15c to 16c; no amber on market. Extracted, 8c to 9c. Beeswax scarce, steady demand, 25c to 26c. W. R. CROMWELL PRODUCE CO.

Successors to C. C. Clemens & Co.

ALBANY, N. Y., March 23.—Honey market is slow on all grades of comb honey. Extracted, white, 7c to 8c; dark, 5c to 6c. H. R. WRIGHT.

BOSTON, March 21.—Fancy No. 1 white in cartons, 17c; A No. 1, 15c to 16c, with a fairly good demand. Absolutely no call for dark honey this year. Extracted, white, 8c to 9c; light amber, 7c to 8c. Beeswax, 27c. BLAKE, SCOTT & LEE.

SAN FRANCISCO, Feb. 6.—White comb 13c to 14c; amber, 11c to 12c; dark, 8c to 10c. Extracted, white, 7c to 8c; light amber 6c to 7c; amber, 5c to 6c. Beeswax, 26c to 28c.

Considering the light output of honey last spring from California, the present offerings are of tolerably liberal volume and are mostly of amber grades. The market is slow at the quotations. It is reported on good authority that the Southern and Argentine countries are doing deal out in considerable quantity, which accounts in a great measure for the very limited business doing in the pure article.

1901—Bee-Keeper's Supplies!

We can furnish you with The A. I. Root Co.'s goods at wholesale or retail at their prices. We can save you trouble and money. Most of the price paid for beeswax. Send for our 1901 catalog. M. H. HUNT & SON, Bell Branch, Wayne Co., Mich.

Please mention Bee Journal when writing.

The Danzenbaker Hive.

THIS HIVE is rapidly gaining favor, especially in the Eastern States, where tall sections and closed-end frames are used to a considerable extent; and within the last year or so the Danzenbaker system has been working its way into California, Oregon, and even into Cuba. At the Paris Exposition the hive was awarded a gold medal, and at some of the honey exhibits in this country the comb honey from it has carried off the first prize. Some of the finest honey we have ever seen was produced in Danzenbaker sections; and in the opinion of those who have given the hive and system an extended trial, there is nothing to equal it for the production of a fine article of comb honey. Indeed, in some markets comb honey in Danz. sections commands one and sometimes two cents more per pound than other fancy honey.

Mr. Danzenbaker has long been an advocate of warm supers and warm hives; for he has always insisted that, for the production of comb honey, the super and hive must be warm in order to do the best work in wax-building. To a very great extent the Danzenbaker hive is double-walled; and the sections in the super are especially protected by a special paraffine mat which goes with every hive.

The brood-chamber itself has the same dimensions as the regular 10-frame Dovetailed Langstroth hive, except that it is shallower; that is, it takes 10 closed-end brood-frames 7½ inches deep and 17 inches long. Each brood frame is supported by a pivot in the center of the end-bars, so that it may be readily reversed. These brood-frames retain all the advantages of frames peculiar to this class; viz., being reversible, they insure the building of combs to the bottom-bar; as there is no opportunity for air-currents around the ends of the frames, combs, as a rule, are built clear out to the end bars. This one feature makes them warmer for winter. When a division-board is used on each side we have, practically, a dead-air space around the ends and sides of the brood nest.

The Danz. brood-nest has the same capacity as the 8-frame Dov. hive—a capacity that has generally been recognized as the best for the production of comb honey. But Mr. Danzenbaker has gone further by making his brood-nest shallower and wider—increasing the amount of surface for the super, and bringing the brood itself—a feature which many consider important—closer to the surplus.

The Danzenbaker brood-chamber can be used, with any of our 10-frame supers, either comb or extracted; with any of the 10-frame covers, bottoms, or hive-stands, or with the 10-frame Jumbo hive. There are four patents on the Danz. hives and fixtures.

NOTICE. The Danzenbaker hive is not made in the 8-frame widths.

THE A. I. ROOT CO., Medina, Ohio.

GEORGE W. YORK & CO., 144 & 146 Erie Street, are headquarters for ROOT'S BEE-KEEPERS' SUPPLIES IN CHICAGO. Send to them for their free Catalog.

AMERICAN BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., APRIL 11, 1901.

FORTY-FIRST YEAR
No. 15.

WEEKLY

MISS ADA L. PHOKARD,
Secretary of the Wisconsin State Bee-Keepers' Association.

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & CO.

144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, \$1.50 a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec 01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

Reformed Spelling—The American Bee Journal adopts the Orthography of the following Rules, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "v" affects a preceding sound. Also some other changes are used.

National Bee-Keepers' Association

OBJECTS:

- To promote and protect the interests of its members.
- To prevent the adulteration of honey.
- To prosecute dishonest honey commission-men.

EXECUTIVE COMMITTEE.

ERNEST R. ROOT, President.
R. C. AIKIN, Vice-President.
DR. A. B. MASON, Secretary, Toledo, Ohio.

EUGENE SECOR, General Manager and Treasurer, Forest City, Iowa.

MEMBERSHIP DUES, \$1.00 a year.

The Bee-Keeper's Guide;

Or, Manual of the Apiary.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipped, or his library complete, without THE BEE-KEEPER'S GUIDE.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to GIVE AWAY to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year.

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO NEW SUBSCRIBERS to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,
144 & 146 Erie Street, CHICAGO, ILL.

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2; or, one Tested Queen free as a premium for sending us FOUR new subscribers (with \$4.00).)

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation—"first come, first served"—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

28 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 28 cents a pound CASH—for best yellow, upon its receipt, or 30 cents in trade. Impure wax not taken at any price.

Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO.

Best White Alfalfa or Basswood Extracted Honey

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are boxt.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

ESTABLISHED IN 1861 AMERICAN THE OLDEST BEE-PAPER IN AMERICA BEE JOURNAL

41st YEAR.

CHICAGO, ILL., APRIL 11, 1901.

No. 15.

* Editorial Comments. *

Make Haste Slowly is very good advice. Mr. Doodittle, in the *Progressive Bee-Keeper*, says: "Being hasty in adopting new methods and ideas is unwise. Test them thoroughly before entering into them largely. Heavy investments, once in a great while, give large returns, but only too often failure follows, unless one makes haste slowly. Especially is this true of apiculture." Verily, the one who is wise enough to hasten slowly is likely to be here longer, or have the larger success with bees.

Sowing Sweet Clover Seed.—As several of our readers have requested directions for sowing sweet clover seed, we will quote from those who have had much experience, as reported in *Gleanings in Bee-Culture*:

Mr. H. R. Boardman, of Huron Co., Ohio, writes this paragraph:

"For field culture I would sow sufficient seed to get a good liberal catch, and not sow more land than I could do to do this. Half a bushel hitch three horses to it, and pull it to the field. The spring of the year I think the best time to sow it. It will make a good catch on winter wheat or rye ground, but I think I should prefer to harrow or cultivate it in deep with a light crop of oats."

Mr. G. J. Yoder, of Cass Co., Mo., gives the following about where sweet clover should be sown, and something about cutting and thrashing the seed:

"It will grow almost anywhere, even on very rocky hillsides and waste lands, but I prefer to sow where I can keep control of it and get a crop of bloom and a crop of seed; then the next spring a crop of some kind, and in the fall a crop of hay, or to wheat in the fall, and in the next fall a crop of hay."

"Every other year it reseeds itself; but if put to cultivated crops a few years it can all be killed out. I made a garden-spot on a sweet-clover patch where there were millions of seeds, and in two years it was all gone."

"With us it grows from four to eight feet high, thus making it almost impossible to get it into a thrasher or huller. We cut it with a self-rake reaper, then make a platform on a 16-foot hay-rack, placing it on a skid made of poles bolted together with cross-pieces; then it is hauled to the field, and pulled to the field. With two light poles about eight feet long, and just heavy enough for a man to handle, and two pitch-forks, we are ready for business. Now fill your platform, not too full; and if the clover is very dry, a few good strokes will land the seed in the bottom of the platform. Now tumble out the refuse; drive up, put more on, and so on around the field. A little experience will show how it should be done. When all is thrashed off, run it thru a huller, and you have the Bokhara seed."

Mr. Wm. Stolley, of Hall Co., Neb., in an article in the *American Bee-Journal* for the year 1895, wrote this paragraph:

"Treating mellilot exclusively as a forage-plant, I will say that I have sown 15 pounds of seed to the acre, and secured a good stand. I have sown early in the fall, so as to insure good rooting of the young plants before frost; and I have sown also late in winter, so as to allow the seed to take advantage of the early spring moisture, with the same satisfactory results. Even the stubble of small grain, or a corn-field, is good enough for sweet clover without further cultivation, except a slight harrowing, and it will take care of itself in this part of the world. I have frequently scattered the seed indiscriminately on vacant places, along public roads, where noxious and worthless weeds were growing, and three years later the sweet clover had run out the weeds entirely. But let me state right here, that sweet clover growing on and alongside of public highways should be cut about June 20th, so as to dwarf the growth of the plants. If this is neglected, sweet clover is likely to grow so rank and high as to make it a nuisance in winter, by causing the drifting snow to bank up, thus making the public roads impassable. Many rank weeds, however, generally growing now on public roads, are just as objectionable in this respect as sweet clover. By mowing it the middle or 20th of June (not later, if the aim is to

make it profitable for the apiarist as a honey-producer), sweet clover will furnish bee-pasturage until frost kills all growing vegetation, and is not objectionable in any way to anybody if growing on the public highways; on the contrary, it is attractive, its perfume is delicious, and it keeps the roads in good condition. In a mild and late autumn I have seen mellilot thus treated, blooming in December, and the bees at work on it here in Nebraska."

The National Bee-Keepers' Association.—In pursuance of suggestions offered some time ago, and also because of the real need existing, General Manager Secor has gotten out a neat circular containing the Constitution of the Association on one side, and "A brief outline of the rise and progress of bee-keepers' societies in America, and the aims and purposes of the present organization." While every bee-keeper can have a copy by simply asking Mr. Secor for it, we believe that his epitomized statement concerning the National Bee-Keepers' Association and its predecessors is of sufficient interest to deserve a permanent place in these columns. It reads as follows:

RISE AND PROGRESS OF BEE-KEEPERS' ASSOCIATIONS IN AMERICA.

The first American bee-keepers' society, of which I can find any record, was organized at Cleveland, Ohio, March 15, 1860.

At that time there were no periodicals devoted to the pursuit of bee-keeping, the *American Bee Journal* having been established later—in 1861.

The first American bee-keepers' society of national importance was organized at Indianapolis, Ind., Dec. 31, 1870. It was called the "North American Bee-Keepers' Association," and included the United States and Canada. The Rev. L. L. Langstroth, of blessed memory, was its first president.

The following year the name was changed to "North American Bee-Keepers' Society," under which name it continued until 1888, when it was changed to "Inter-National Bee-Association."

When the above-named society was organized scientific bee-keeping was in its infancy. The annual meetings held were beneficial chiefly for their educational value. No conflicts had arisen between fruit-growers and bee-keepers, and the adulteration of honey had not become a menace to the industry because commercial glucose was unknown.

BEE-KEEPERS' UNION.

But in the year 1885 a Wisconsin bee-keeper, Mr. Freeborn, was sued by a neighbor who kept sheep, for alleged annoyance to his flock by Mr. Freeborn's bees. As the Constitution of the Inter-National Association did not provide for the defense of its members, an independent organization was formed for that purpose, called the "National Bee-Keepers' Union." This "Union" never held a meeting, all its work being done by correspondence, and the annual report of its General Manager published thru the bee-journals. From 1885 to 1890, inclusive, its General Manager, Thomas G. Newman, was ever alert to the dangers threatening bee-keepers, and to the extent of its limited resources was very efficient in their defense. The successful defense of Mr. Freeborn, the vindication of California bee-keepers when attacked by ignorant or jealous fruit-growers, the magnificent triumph in the Arkadelphia case, and many others, where the above-mentioned precedents were quoted effectively, thus avoiding lawsuits, vindicates the wisdom of its organization.

In the year 1896 the Inter-National Society voted to change its name to the "United States Bee-Keepers' Union," and adopted a new Constitution, making it protective in its aims, as well as educational and social, and for three years both "unions" worked along similar lines of defense, altho the last-named Union was also aggressive, and proposed to fight adulteration.

AMALGAMATION.

But in December, 1899, the two unions consolidated under the new name of "National Bee-Keepers' Association." What the latter has done since its marriage, and what the United States Bee-Keepers' Union did before amalgamation, has been made public thru the annual reports of its General Manager, but it may not be out of place again to call attention to its aims and purposes, and to some of its most important cases.

The present Constitution defines the objects of the Association to be: 1st, "To promote the interests of bee-keepers." The educational work of the Association is intended to benefit the pursuit of apiculture in the broadest sense, especially in our own country. This object will not have been reached until every bee-keeper within the bounds of the

Association's influence defies every possible profit and delight out of his bees.

24.—*To protect and defend its members in their lawful rights.* We maintain that bee-keeping is a lawful and honorable occupation, as old as history, and as much deserving of protection as any other rural pursuit, but ignorance and jealousy are not yet outgrown, and bee-keepers are sometimes annoyed and threatened unless they understand and maintain their rights. An efficient organization can do much good toward this end, as has already been proven.

30.—*To enforce laws against the adulteration of honey.* This is a matter that needs and is receiving the aid and encouragement of the Association. Pure food is of vital importance, and where the legislature of any State has enacted laws to protect the purity of honey, this Association purposes to spend money if necessary to enforce them. Pure honey can not be produced and sold in competition with glucose syrup, and as this substance is the chief adulterant of honey, there is need of anti-adulteration laws in every State, and strict enforcement of the same.

SOME OF THE THINGS THIS PRESENT ORGANIZATION HAS DONE.

It has endeavored to prevent quarrels and litigation. The present Manager is for peace if it can be obtained honorably. He does not carry a chip on his shoulder daring some one to knock it off. He tries to avoid troublesome lawsuits, and believes he has done so in many cases. This doesn't bring any glory to the Association, but it is beneficial and praiseworthy nevertheless.

With that object in view, a 12-page pamphlet on the benefits of bees to horticulture, and the danger and uselessness of spraying when trees are in bloom, has been prepared for distribution where needed.

Many jealous neighbors have been deterred from threatening attacks on bee-keepers by judicious circulars and letters.

The aid given by this Association to prosecute adulterators of honey in Chicago, in 1899, had a wholesome effect, as we have been credibly informed. If not all was accomplished which was desired and aimed at, the results hastened the branding of adulterated honey in that city, so as to denote its true character.

During the fall of 1900 there appeared in many of the Eastern papers highly sensational accounts of a lawsuit between a fruit grower and bee-keeper in the State of New York. The contention was that defendant's bees had ruined plaintiff's crop of peaches. In justice court the bee-keeper lost. The Association had the case appealed, and after a thorough trial, at which every argument and artifice known to skillful lawyers was resorted to by plaintiff, the Association produced enough expert evidence to completely turn the tide, and the bees were exonerated. Had this case gone the other way there is no knowing how many other bee-keepers would have had to quit business or defend a like suit.

The winning of this case, and the valuable precedent established, which will be quoted in all the courts of the country for years to come, is a triumph for the National Bee-Keepers' Association, and worth many times its cost.

If an Association for mutual protection and the general advancement of the art and science of apiculture meets with the approbation of any bee-keeper who is not already a member, he is hereby invited to co-operate.

The annual membership fee is \$1.00. It may begin at any time desired, and the amount sent to the undersigned will be duly entered and acknowledged.

Forest City, Iowa.

EUGENE SEFOR,
General Manager and Treasurer.

The Number of Drones Needed in an apiary is a thing upon which all are not yet agreed. At this time of year, when one begins to plan for the next season, it may be well to make an effort to have one's ideas somewhat settled on the subject, so as to know whether to encourage the production of drones or to discourage it by controlling the kind of comb in the hive. Mr. Dadant's series of articles on this subject will be of great service in the way of helping to decide this question.

The first objection likely to be urged against allowing the presence of many drones is that it is allowing a horde of useless consumers that add nothing to the common store. But if they are of service in other ways, they may earn the food they eat without gathering it for themselves.

It can not be denied that drones may be of real service to help keep up the heat of the colony, but it is replied to this that in the winter, when there is the most need of heat-producers, the drones are wanting, and when they are present in numbers the weather is so hot that a set of fanners must keep at work to make their lordships comfortably cool. Further, it is argued that a pound of workers are just as useful in keeping up the heat as a pound of drones; so the argument for drones as heat-producers is hardly valid.

In an apiary of 50 colonies thousands of drones are flying that are never needed. Why not restrict the number to the 50 or 150 that will actually need the virgin queens? The answer is not difficult. With the large number always present, it has been many times observed that a virgin makes a successful flight not until the second or third attempt. If no drones were in the air except the one she was expected to meet, the chance of such meeting would be rather small, and the chance of being caught by some bird rather large. Besides, when a large number is present, there is a chance for selection. The most active and

vigorous drone is the successful one, and this tends to the improvement of stock. One has but to observe Nature to note that each colony has a large number of drones, and it may not be wise to make so violent a departure from Nature as to suppress nine-tenths of the drones she would provide.

But it is a departure from Nature to mass 10, 50, or 100 colonies in one place, and no more drones are needed for the whole lot than would be needed for a single colony. Consequently the drones may be restricted to two or three of the best colonies, thus adding greatly to the selection of the best.

So the probability is that in the average apiary there need be no anxiety lest there be a lack of drones, and the wise bee-keeper will take advantage of this by seeing that no drones are encouraged in mediocre colonies, but that they are suppressed in all but a few of the very best. If more attention were given to this, there would be a distinct increase in the average yield of honey per colony.

* The Weekly Budget. *

Frank B. White.

THE FRANK B. WHITE COMPANY, of Chicago, is one of the cleanest and most honorable advertising firms in the world. It is an organization of young men who are banded together to handle the advertising for such firms or business men as desire to use the columns of the general agricultural press. Mr. Frank B. White is the much-respected president or head of the Company, and a man whom to know is to love. Recently he conceived the idea of tendering a dinner or banquet, and sent out invitations, the following being a sample:

CHICAGO, March 20, 1901.

MR. GEORGE W. YORK, Editor American Bee Journal.

Dear Sir:—I desire to give my business associates, and those occupying the more responsible positions in connection with our business here, a dinner at the Union League Club, Thursday evening, March 21st, at 6:30 p.m., and I trust nothing will prevent your being present.

Very truly yours,

FRANK B. WHITE.

Of course we were there, and it was a most delightful occasion. After doing full justice to the bounteous and tempting viands placed on a circular table before the assembled guests, several hours were spent in "after-dinner" toasts or short speeches. There were about 20 of the employees of the firm present, and those financially interested. Each department of the rapidly developing business was called on to respond to an assigned topic, and each indicated the sprouting of Chamney Depew wings of eloquence and wit. Mr. White, as host, speaking first.

The last speaker was the editor of the American Bee Journal after which one of the prominent employees presented to Mr. White a written and signed expression of appreciation and esteem in which he is held by all the employees. It was a sincere testimony, and one highly prized by the recipient, who merits all the kind things that were said of him on that enjoyable occasion.

MR. C. THELMANN, of Wabasha Co., Minn., about six weeks ago met with a serious accident, his horses running away with him in a sleigh. He was thrown out on a lot of logs lying along the roadside, while the horses were going at a furious rate of speed. They were frightened by dogs running against them, causing them to become unmanageable. While no bones were broken, Mr. T.'s neck and hips were badly bruised and strained. He is improving slowly, and we are glad to report, and all will unite in the hope that he may soon fully recover.

Prof. Cook, having been quite sick recently accounts for the non-appearance of "The Home Circle" department in several issues. He has recovered now, so we trust that all may go on again without further interruption after this week.

Convention Proceedings.

Report of the Wisconsin Convention.

BY ADA L. PICKARD.

The 17th annual convention of the Wisconsin Bee-Keepers' Association was held at Madison, Feb. 5 and 6, 1901.

The meeting opened with a fair attendance considering the small honey crop the bee-keepers secured last year, and the number of Wisconsin bee-keepers who attended the national convention held in Chicago.

Pres. N. E. France asked the convention to come to order, and opened the meeting with well-chosen remarks, after which the secretary read the minutes of the last meeting, which were approved.

The opening session was largely devoted to the discussion of a bill which had been introduced in the Wisconsin Assembly, providing that the number and value of the colonies of bees be inserted in the assessment rolls, the same as other personal property. The bill further provided that if colonies of bees be moved about from place to place for the purpose of extracting honey, the owner shall pay a license fee of \$1.00 per colony for each month or part of months. When that bill was introduced the State bee-hive was klickt, and each individual made a great roar. The bill was discussed very thoroughly. The bee-keepers did not object to the taxation of bees as the majority now pay taxes on their bees, but it seemed that the assessment varied greatly, and seems very unjust. Throughout the State bees have been assessed from 25 cents to \$1.50, and even as high as \$2.00 per colony, according to the one who was assessor. The unanimous voice of the bee-keepers favored the taxation of bees, for if bees were taxable property we could claim protection from the State.

It was the latter part of the bill to which the objection was offered. On motion a committee was appointed by the president for the purpose of going before the legislative committee to oppose the bill. The committee appointed was: N. E. France, Jacob Hoffman, Elias Fox, and Ada L. Pickard. At an appointed time the committee went before the legislative committee, and thru the work of the committee and the united efforts of the Bee-Keepers' Association, the bill has been indefinitely postponed—virtually the bill is killed.

At the close of the discussion pertaining to the bill the convention stood adjourned until 1:30 p.m., when Pres. France called the meeting to order, and, on motion, Editors Hutchinson, Root, and York were made advisory members.

WINTERING BEES.

H. P. Miner read a paper on "Cellar vs. Outdoor Wintering," after which was a lively discussion. Mr. Lathrop said he had wintered bees both ways, but preferred the single-wall hives in cellars to the chaff hive. Mr. Ochsner favored the chaff hive for winter use, but not for summer, as he has had losses in combs and honey, from the fact that the chaff hive gets so hot during the hot weather, causing the combs to melt down. If chaff hives were used in winter, he suggested that they be transferred to single-wall hives in May. The discussion was summed up in not so much how or where to winter the bees, but to strike the key-note of success depends upon getting the workers at the proper time for your location.

A recess was given the members for the opportunity of paying the dues to the State and National Associations, and the dollars rolled in almost faster than the secretary could book the names.

H. Lathrop read a paper on "How to maintain the present prices of honey in the event of a good honey crop." In speaking of the good prices of honey he said, "Dealers go thru the country and buy up the honey from small producers, put it up in good shape and sell it for a good price. It is better to sell to the jobber if not willing or able to hold for good prices; never sell at low prices to retailers."

QUES.—Is there any simple method of detecting adulteration in extracted honey? ASS.—Mix equal parts of honey and wood-alcohol together; stir until thoroughly mixed. If sample contains glucose it will turn cloudy, if not it will remain clear. It does not make any difference what kind of honey you test.

QUES.—How can aster honey be kept from granulating within ten days after storing, regardless of temperature? ASS.—Do not know.

QUES.—Where is the proper place to keep extracted honey? ASS.—In a dry place.

QUES.—What is the best package for extracted honey? ASS.—(a.) The best package for storage and shipping is barrels. It has been found a great advantage to paraffine the barrels before using as it saves leakage. The cost to paraffine a 350-pound barrel is about 10 cents. (b.) The best package for retail trade is the 60-pound tin cans, or pails holding 4, 7 and 13 pounds each.

QUES.—Does it pay to crate comb honey? ASS.—Yes. But the cases should be crated properly with plenty of straw for packing.

QUES.—How many combs should be left in an 8-frame hive for cellar wintering? ASS.—Majority favored eight.

QUES.—Is it advisable for the State Bee-Keepers' Association to recommend an experimental apiary in Wisconsin? ASS.—Yes. It was recommended that the Association recommend an experimental apiary on the experimental farm. Mr. France offered to donate his services if such an apiary should be started. A committee was appointed to visit the experimental station, composed of N. E. France, Jacob Hoffman, and Ada L. Pickard.

An adjournment was then taken until 7:30 p.m., when the convention was most highly entertained by Editors E. H. Root and W. Z. Hutchinson, who presented their instructive and entertaining stereopticon views, which must be seen to be appreciated. Those who saw the views expressed themselves as being well paid for attending the convention, save the valuable information received from the papers read and discussions which followed.

SECOND DAY—MORNING SESSION.

The morning session opened at 9:30 with a bus news program. The report of the treasurer was read and approved. The election of officers resulted as follows: President, N. E. France; vice-president, Jacob Hoffman; secretary, Ada L. Pickard; Richard Center; treasurer, H. Lathrop.

The judge and alternate judge of the apianian department of the State Fair were named—F. Wilcox as judge, and N. E. France as alternate. On motion, the secretary cast a ballot recommending N. E. France as inspector of foul brood.

BEE-KEEPERS' HONEY EXCHANGE.

The secretary read a paper on "The Bee-Keepers' Honey Exchange," by C. A. Hatch, which was listened to with great interest. Mr. Root opened the discussion and mentioned the Colorado Bee-Keepers' Exchange, and said it was a good thing, enabling the bee-keepers to get supplies cheaper, but a bad thing for the supply dealer. The first thing to make the exchange a success is to have a good business man as business manager, who has the interest of every one in mind. It was thought not advisable to organize a honey exchange in this State, because the ones attending the conventions have a chance to keep in touch with the prices.

E. D. Ochsner did not read his paper on "The Outlook for the Bee-Keepers' Exhibit at the Pan-American Exposition in 1901," because an expression of the convention was taken in regard to making an exhibit, and it was thought not advisable to make an exhibit because the appropriation is so small.

F. Minnick read his paper on "Short Cuts in Extracting." It was received with much enthusiasm. A very interesting discussion followed, and many new ideas were advanced. The afternoon session was opened by Pres. France reading and discussing the laws pertaining to foul brood.

The question-box being full, it was again opened.

The agent of the Citizens' Business League, of Milwaukee, gave a very cordial invitation for the next meeting of the Association to be held in Milwaukee. On motion, the executive committee was authorized to name time and place where the next meeting shall be held. The members favored Madison.

The convention then adjourned *sine die*.

ADA L. PICKARD, Sec.

[The interesting papers read at the above convention will appear later, so far as we are able to secure them.—EDITOR.]

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song, words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

No. 2.—Practical Lessons for Beginners in Bee-Culture.

BY J. D. GEHRING.

(Continued from page 199.)

AT the dinner table my wife past the honey to Mr. Bond, saying as she did so: "Honey is almost as indispensable at our table as butter, Mr. Bond. We use it at the rate of a pound per day the year thru. My husband thinks it is both food and medicine. Our children all like it, and grow fat on it. I presume you are a bee-keeper, too, Mr. Bond," she concluded, looking at him for his answer as she spoke. Mr. Bond, however, looked at me when he answered and said:

"I guess Mrs. Gehring thinks because you have entertained me in the honey-house I must belong to the bee-keeper fraternity; but I am quite sure that if she had seen me when I was running into her cellar with several hundred bees after me, she wouldn't have made such a bad guess." Then, turning to my wife he continued:

"Mrs. Gehring, if you had asked about the matter before 10 o'clock this morning I would have said yes. But I am now of the opinion that I am only a keeper of bees, not a bee-keeper. But I am going to take lessons of your husband. He convinced me this morning that I have a lot to learn. The fact is, I never knew until to-day that there is such a creature as a queen-bee. I inherited most of the bees I have on my farm from my father, and I guess he knew no more than I did this morning about bees, for I remember hearing him mention the 'king-bee,' but never the queen-bee, of the hive. He had some very queer notions about bees, as the Pennsylvania Dutch all have—and I never knew one that didn't keep a colony or more. You may have heard about their superstitious notion that when any one dies in the family all the bees will die, too, unless some one goes out at midnight and whispers the sad news to each hive."

"How many colonies of bees have you now, Mr. Bond?" I inquired.

"There are some 45 or more. They are not all in one place, like yours, so I can't tell exactly how many there are. You see, I have always been in the habit of leaving them just where I found the swarm when I hived it. My hives are all the old style that my father used—square boxes with cross-sticks in them."

After dinner Mr. Bond returned with me to the honey-house, and, at his request, I took him to the honey-room and showed him my 1,600 pounds of honey, all in one-pound sections, and packed in cases ready for the market. After a minute's contemplation of the stack of white boxes, Mr. Bond exclaimed: "Never, in all my life, have I seen so much beautiful sweetness!"

Returning to my work-room, Mr. Bond turned to me, before he sat down, and said:

"Now, then, Mr. Gehring, will you please tell me, as briefly and plainly as you can, how you manage to get at the rate of 100 pounds of honey to the colony, and inside of 30 days' time?"

"I can tell you plainly enough how it is done," I replied, "but I fear I am not equal to the task of telling it very briefly. It is quite a lengthy and complicated story, Mr. Bond. The best way will be, I think, to take one hive as an object-lesson, and illustrate the whole story as I go along. To do that, however, it will be necessary for you to go with me to the spot where the hive stands, so that I can explain everything to your eyes, as well as to your ears. What do you say to my plan, Mr. Bond?"

Mr. Bond did not reply as promptly as I had expected he would, having in mind his manifest enthusiasm. He looked meditatively at the floor between his feet, twirling his straw hat slowly with his right hand, while with his left he gently stroked his nose, which, by the way, had not quite regained its normal size and color. At last he looked up and said:

"Your plan is no doubt all right so far as you are concerned; but it looks a leedle bit risky-like for me. You see, I can't quite forget my little unpleasantness with your 'well-behaved bees' this morning."

"I can't blame you for that, Mr. Bond," I replied. "But I shall fit you out with a bee-knight armor that thoroly protects your face. Your hands you can put into your pockets, if any attack is made on them." Saying this I procured from a small closet two bee-veils and a Bingham bee-smoker, and, handing one of the veils to him, I said:

"The right kind of a bee-veil is a valuable article to any person who has to handle bees under all sorts of circumstances. This is my own invention, tho' not patented. I have seen some that are patented that I wouldn't have as a gift. This one, you see, is a very simple affair, not much larger in bulk than a cotton handkerchief. I will tell you how to make one like it, then you can get the material before you go home, and show your wife how to make one:

"Take half a yard of cheese-cloth and double it lengthwise. Sew up the open side about half way. Cut the other side open to correspond with the length left open. Hem or bind the raw edges. Insert a rubber-cord into the end intended for the top, short enough to fit tightly around the crown of your hat, like a pucker-string. Now take a piece of silk bobbinet large enough to reach from the middle of your forehead to your chin, and from one ear to the other, and insert it in a square hole in the front of the upper end of your cheese-cloth sack in such a way that when the veil is in place the little silk veil is directly in front of your face. The open end of the veil—as the whole contrivance is now called—is carefully tucked inside your vest, or your coat when you wear one—which is then buttoned up, and—there you are! Your hat-rim should not be very wide, of course, unless you make the veil a little longer than I have described. The meshes of the silk bobbinet should be rather fine, but not too close to obstruct your vision."

"Now, when you call for this bobbinet stuff at the store the clerk will possibly tell you that the cotton kind will do just as well, and is cheaper. But, let me caution you, never allow any one to induce you to take anything but just what I have told you. If you ever do, you will find out why I have warned you, without my telling it now."

"Now," I continued, "I will start this little machine we call a smoker, and then we are ready for business. Let me show you how to manage the thing properly, Mr. Bond. First, you see, I remove the end, or nozzle, taking care not to let the circular screen fire-guard drop out as I do so. Next, I take a cotton or an old linen rag, light it with a match and drop it to the bottom of the cylinder. Then I carefully drop in some more rags, gradually filling the smoker, but rather loosely, so that the fire is not extinguished. I leave the smoker standing nozzle-end upward all this time, you see, because in that position it acts like a chimney. When it is full and well started I replace the nozzle, put a handful of fuel-rags in my coat-pocket, take the smoker and give it a few gentle puffs, and off we go."

On the way to the hive I said to Mr. Bond: "All the bee-books in use recommend the use of broken corn-cobs or punk wood as smoker-fuel. But I don't like either. Both are liable to become damp, and they are not as easy to start as rags are. Besides, when they once get under full headway in the smoker they make too much heat. When I need a smoker in a hurry—and that is almost always the case—I give me cotton-rags for smoker-fuel every time."

"Well, here we are," I said, proceeding to remove the cover of the hive I had selected for the purpose in hand. Then taking the smoker and giving it two or three vigorous puffs to start a good volume of smoke, I went to one side of the front of the hive and blew smoke into the hive thru the bee-entrance for about 30 seconds, working the bellows of the smoker with slow, steady pressure, so as not to alarm the bees with the puffing noise made by the smoker when worked with a short, quick motion.

"This I do to induce the bees to fill themselves with honey," I explained to Mr. Bond, who was standing a few feet away with his hands in his pockets, watching the proceedings. "We will now wait a few minutes until they have gorgeed themselves."

"What do you do that for?" asked Mr. Bond. Instead of giving him a direct answer I said, "Come and put your ear down near the top of the hive and listen for a moment." Mr. Bond did so, rather reluctantly, of course, and I said:

"You hear them make a humming noise, don't you? Well, they make that noise to express their satisfaction. It makes them lazy and good-natured when they are full of honey. Bee-keepers know this, and take advantage of the fact when they have a tedious job of manipulation to perform in the apiary. These bees, you see, will be less liable to fight now, or to take wing and give the alarm signal to the hives close by."

(To be continued.)

Weak Colonies in Spring—When to Unite Them.

BY G. M. DOOLITTLE.

A CORRESPONDENT writes that many of his colonies of bees will come out weak this spring, and wishes me to tell him in the American Bee Journal when and how to unite them.

When colonies of bees come out weak in the spring, it may be beneficial to put two or more of these weak colonies together, so that one strong colony may be made from several weak ones. Some suppose that if any uniting of weak colonies is to be done, the earlier in the spring it is accomplished the better the results will be, but from years of experience along this line I am positive that such early uniting is a mistake. From some experience several years ago, I came to the conclusion that each would go thru the early spring better alone, and to test the matter I tried the following one spring:

I had ten weak colonies and united six in one hive, three in another and left one alone, which was scarcely an average of the whole, as to strength of bees. This uniting was done the latter part of April, and in less than three weeks' time the colony formed by uniting the six was all gone. During the same time the one not united "held its own," while that where the three were put together was scarcely better than was this.

On June 10th the one having no help had by actual count 85 bees besides the queen, and the one made from the three had 105, according to an entry I find in my diary. As I was then anxious for all the bees I could get, I did the best I could with them without help from other colonies. The one having the 85 bees built up and stored five sections of honey, besides having enough for winter, the same coming from buckwheat. And other experiments made since then gave like results, so that, of late years, I have ceased altogether to unite early in the spring.

After a careful watching I find the reason for this seemingly inconsistent state of things to be, that with united colonies the bees seem to be incited to greater activity, by strange bees being thrown together, thus starting a large lot of brood, the care of which wears their life out so fast that they perish from exhausted vitality, or old age, before any young bees emerge from their cells to take their places; while those not united do very little, and rear only enough brood to take the places of those slowly dying off, thus keeping their numbers about good till settled warmer weather comes, when these few (now) young bees are able to hold five times the brood they could in early spring, so that they now increase rapidly.

From the above it will easily be seen why I would not unite weak colonies early in the season. Of late years I have united just before the honey harvest, as I consider it more profitable than to let each colony go thru the season separately, as I did the one having the 85 bees. If these colonies are left to themselves, the best we can hope is that they will become strong enough in bees and honey for winter; while by uniting just before the honey harvest I secured a good yield of honey from the united colony and got the two in good condition for winter. My plan of work in uniting, and looking toward this end, is as follows:

As early in the spring as the bees can be looked over, all of the weaker colonies are shut on as few combs as they have brood, by using a division-board to contract the hive. They are now left till warm weather comes, being sure that all have stores enough where they can conveniently reach them to carry them until this period. They are now built up as rapidly as possible by reversing the brood, etc., so that by June 1st the best of them will have five frames of brood, others four, and so on down to one for the very weakest. As soon as the best has its five frames filled with brood, down to the very bottom corners, a frame of hatching brood is given to one having but four frames, and an empty comb put in its place.

In taking a frame of hatching brood in this way I generally take all the bees there are on it right along, only being sure that I do not get the queen, so that all the young bees on this comb help to give strength to the weaker, as the younger bees will not return to their old home.

In a few days a frame of brood and bees are taken from each of these two five-frame colonies, and given to the one having but three frames, and so I keep taking till all have five frames each.

Do not make the mistake some do and try to strengthen the very weakest first, for by so doing from one-half to two-thirds of the brood will be liable to perish with some

cool spell, as these last colonies have at this time all the brood they can properly care for.

By the above plan we are always safe, and advancing warm weather is in our favor also. In a few days after all have five frames of brood, we are ready to unite, and if all has been done as it should be, the uniting will be done about the time white clover begins to yield honey nicely.

To unite: Go to No. 1 and look the frames over till the queen is found, when this frame having the queen on it is set outside the hive. Now spread the frames apart in No. 2, when the four frames of brood, bees and all, from No. 1 are carried and placed in each alternate space between the frames of No. 2, closing the hive. Return the frame having the queen on it to No. 1, placing beside it an empty comb; adjust the division-board and the work is done. In two or three days, put the sections on the hive No. 2, and see what a pile of honey they will store up. At the same time place an empty frame, having only a starter in it, between the two filled ones in No. 1, and in a few days you will have a frame filled with as nice worker-comb as you ever saw, which is much cheaper than to buy foundation. Nearly all the old bees carried to No. 2 will have returned by this time, so that No. 1 is a splendid nucleus, just right for building straight worker-comb, and by giving empty frames as needed this colony will be in good condition for winter, while No. 2 will have given three times the honey the two would have done if left to themselves, or had they been united in early spring.

Onondaga Co., N. Y.

No. 14.—Interesting Notes on European Travel.

C. P. DADANT.

I THOUGHT that I had well-nigh exhausted the narration of my trip, but our kind editor has the desire of inserting in the American Bee Journal a photograph of the birthplace of my father, Chas. Dadant, which was secured from the collection of an amateur photographer who has been dead many years. This photo was taken some 40 years ago, and it would appear, from the half-tone, that the original picture was good, altho evidently taken on a windy day, if we judge from the appearance of the trees in the view.

It was on the 22d of May, 1817, that my father was born, 84 years ago, in the large house at the back of the picture. The nearest building on the left hand was a blacksmith shop, and you can readily see two large grindstones under a brush shed. The church was being rebuilt, and they are putting the new building right over the old one, but the village was short of funds and they had temporarily abandoned the work and boarded up the unfinished portion. The column in front of the church is a public fountain, and it is still there. The near house on the right is a grocery. The houses, the roofs, as will be noticed, are, like their roads, entirely of stone. It takes rafters of wonderful size to bear such a load, and the attic of one of those houses looks like a monstrous structure, but once they are put up, the roofs last till the wood is entirely worn-eaten and the rafters crack under the weight.

The trees at the back of the picture, which seem to flutter in a strong breeze, are on each side of the highway which traverses the village, and the little river is just behind that. At the time when the picture was taken, the public highway was the only means of communication with other towns, but for the last 25 years they have been supplied with railroad facilities, telegraph station, telephones, etc. The church is now finished and is a much finer structure than the one in the picture.

This village, Vaux-Sous-Aubigny, is the one which I mentioned in my second letter, (page 629—1900), as the home of my grandfather, when I was a boy, and which I visited with so much pleasure. I had been told on the way to Europe, by foreigners, who, like myself, had visited the home of their boyhood days, that I would find everything changed, that no one would know me, that those who would remember me would be very indifferent, and that it would be an all-around disappointment. Such was not my experience, altho I had come prepared for a change. In this village as in one or two others where I had been used to visit, and also in the city of my birth, some 20 miles from there, I found plenty of friends, old and new. As a matter of course, the new friends were all apiarists. The treasurer of the old college is an apiarist of some note, and I made his acquaintance with the greatest pleasure. He took pride

in showing me, on his desk, a copy of our French "Langstroth Revised," with my father's autograph.

In one of these little villages, not far from the one in the picture, I met a man who used to drive a wagon for my maternal grandfather, and with whom I used to ride back and forth, on school holidays, when I was 10 or 12 years old. This man, who was then about 32 to 35, is a bee-keeper, and as such I certainly have a right to introduce him to my readers. I must, however, own that he has none but straw skeps, and is not very progressive. When I went to see him during my last trip, he was out in the harvest field with his hired servant and his wife.

The servant was wielding the cradle, the woman was raking the wheat, and the old man was binding. He is now upward of 70. I walked up to him, he straightened himself and stared at me as in wonder whether the strange visitor was not out of his way. I asked, "This is Mr. V.?"

"Yes, sir; that is my name."

"Well, I am an old acquaintance," said I.

"Oh, I believe you are mistaken, I never saw you before."

"Look at me well; you know me; you have carried me in your arms."

"In my arms? You must have been smaller than you are to-day."

I gave him my name. The poor old fellow hugged me as if I had still been the little boy he had known, and said, "Is that you, my little fellow? and did you come all the way back from America to see your old friends?"

The harvest was dropt for that day. He took me back to the village and we had a good visit, and you may think how much we had to talk about. We went to look at the bees, but did not stay long with them—we had too many other things to see.

Around that vicinity a new impetus is given to bee-culture, for they have an important bee-association, which comprises what is called a "Department," a land division covering about the space of one of the small New-England States. This association is beginning the publication of a monthly bee-paper, "Practical Bee-Culture" (*L'Apiculture Pratique*), which is very nicely gotten up. Whatever they do, the Europeans are not behind in the number of their bee-publications, for, in France alone, there must be some 10 or 12 of them, published in different places. I have nine of them on my desk now, and they are all wide-awake, all bent upon taking the peasants out of the old rut as rapidly as practicable.

But in these ancient places we saw some very queer people, with very extraordinary ideas about America. A friend in our city asked me to come with him to pay our respects to a couple of old ladies who had known my folks long before my birth, and who expect a wish to see me. They were between 75 and 80 years old. My daughter accompanied me and we were heartily welcomed. But the elder of the two ladies after the usual compliments, raised her spectacles, and looking at my daughter with unfeigned astonishment, said: "Why, your daughter is as white as you are!" She had evidently imagined, that, living in that wild country—the backwoods of western America—I had married the daughter of some Indian sachem, some red-skin Pocahontas. This amused my friend, as you may understand, and he laughed heartily, and went to great trouble to explain to these good ladies that America was not peopled with savages only, and that there were a few families of the Caucasian race scattered over that great wilderness.

Now, Mr. Editor, I will close this too-long narration which has been continued thru 14 numbers. I will ask forgiveness of those bee-keepers who have followed me in the hopes of getting a little bee-culture out of all this talk, for they have been sadly disappointed. I will also express my thanks for the many kind words spoken in private correspondence by some who seem to have enjoyed my too-personal recollections of the most agreeable voyage I have ever made.

Hancock Co., Ill.

Birthplace of Mr. Chas. Dadant—Vaux-Sous-Aubigny, France.

(Edition of 1899-1900.)

No. 3.—A Review of "A B C of Bee-Culture."

BY PROF. A. J. COOK.

(Continued from page 197.)

PAGE 277—A word more about bees dying because they have lost their sting. Several times I have had my students secure bees that have lost their sting, it having been pulled out consequent upon use. These were put into a cage and fed. Other bees, uninjured, were put into a cage and fed in the same manner. In two or three days all the first bees were dead, and none of the others, nor were the latter dead for days, even weeks. I would not wish to be understood as holding the view that stinging will necessarily kill a bee, as a slight sting would not pull the sting out and might not do any serious injury. But I believe that when the sting is extracted, it will always end in the death of the bee. The time, however, will vary, which argues that in some cases more injury is done to the internal organisms than in others.

Page 280—I am a little skeptical as regards the queen leading out the bees. I would not be sure that Mr. Root was right in his conclusion. This may have been a normal swarm and the queen may have followed them to the old hive rather than have been led by them. In all my experience, I have never known a queen to lead a swarm. Her presence, however, will have much to do in forming the cluster, as every apiarist of experience knows.

Page 357—I think Mr. Doolittle is a poorer philosopher than he is an apiarist. I should have great respect for any opinion he might give in reference to bee-keeping. I am not at all sure of his dictum with reference to swarming. Surely bees do swarm out of their hive from other cause than the instinct to increase. Indeed, I think the old idea of instinct as being the unvarying and inerrant guide of insects and other of the lower animals in their actions will more and more be modified. I think now that our best naturalists are giving it up. Is not all instinct the result of previous acts guided by intelligence? Acts, repeated many times under volition, result in a habit in which case action becomes almost automatic, hardly guided at all by the will. Action that has long been habitual will after a time become almost unvarying, and becomes, perhaps, wholly automatic. The physiologist would call this reflex action with the gray matter of the spinal cord as a center. With man, and to a less degree with other higher animals, the intelligence often interferes to modify habit and instinct. I believe this is equally true with bees and other lower animals. If I am correct, then swarming will not always follow from the same cause. I think every apiarist will recognize that varying conditions will very greatly modify the habit, or instinct, if you please, of swarming.

Page 362—I was surprised to note that Dr. Miller also gives his authority in favor of bees not clustering in case the queen does not go forth with the swarm. I have always been surprised at such assertions. For many years, I practiced clipping queens' wings, which I believe is always wise policy. I have had hundreds of swarms go forth where the queen was clipped, and so of course could not join them, yet I found it very rare that the colonies failed to cluster. In such cases they will always return to the hive, but in my long experience and observation, it will be

decidedly the exception and not the rule that they return to the hive without forming at least a partial cluster.

Page 299—Mr. Root in referring to turnips writes as follows: "If they are turned under just before going out of bloom, they make one of the most valuable of soiling crops. Thus a good turnip pasturage may be obtained with no extra work except sowing the seed, and the crop will be an actual benefit to the soil if turned under." Has not Mr. Root used the wrong word here? As I understand it, soiling is used to refer to cutting green herbage for immediate feeding. When we cut green corn for our cattle, we are then soiling. Plowing under a green crop, as I understand it, is not soiling but green manuring. I think, also, that no scientist would agree with Mr. Root that turnips are one of the best crops for green manuring. They would add no manurial element to the soil. They would be of advantage in adding humus. They are not very deep-rooted plants and so would not bring up inorganic matter deep in the subsoil. Leguminous crops, like peas, clover, and lupin, root much deeper, furnish just as much, if not more, humus, and in taking the nitrogen from the air and combining it so that it can be utilized for the plant, are the plants par excellence for green manuring. The man who is content to plow under the cereals like oats, barley or rye, turnips or weeds, instead of some legume, like clover and peas, is content with a half loaf when it were just as easy to secure a whole one. This suggestion is all the more valuable in view of the fact that nitrogen is the most expensive fertilizing element which we need to add to our soil.

Page 306—Is it true that all the moisture that is found in the hive, making the sticky mass after bees have been suffocated, comes from honey that the bees have regurgitated? I think there is good reason to believe that much of this is the water of perspiration, or possibly we better say, respiration. In such cases, bees try hard to cool off. The only possible way that they can do it is by evaporation of water. That they function in some way analogous to our sweating, I think there can be no doubt. That perspiration from the exterior of the body can amount to much, is doubtful. Their thick, chitinous crust would seem to make this impossible. I have no doubt that there is much escape of water by evaporation—in fact, there must be—from the innumerable air-tubes. I believe close investigation will prove that such moisture is more in evidence on such occasions than the honey which the bees regurgitate.

Page 308—Here, again, our author refers to bees separating water from honey while on the wing. I believe this is physically impossible. I have never as yet seen this "mist" fall from the bees while flying in the air. The statement has so often been made by others who thought they had seen it that we can hardly doubt but that it had some basis in truth. If such mist does fall from the bees, it certainly must be the water of evaporation in the air-tubes, or else excreta from the intestines. This is certainly a matter which deserves very close investigation.

Page 310—The Chinese wax referred to on this page is the product of an insect. It is one of the scale insects or coccids. Thus it is related to the cochineal insect, which, as is well known, gives us our carmine dye. This Chinese wax is very white and is used for making candles. As Mr. Root well says, it is too expensive to be used to adulterate beeswax, and, more than this, detection would be very easy.

Page 321—In speaking of the willow, it is stated that it does not furnish honey, and the late Mr. Quinby is quoted to the same effect. This is certainly not true of all our willows. As is well known, the willow, like our pepper here in California, are dioecious, that is, the male and female flowers are on different trees. I have seen bees over and over again thick on the blossoms of both. They were visiting, one for pollen and the other for honey. True they might get honey from the willow *Aphis*, a plant-louse which is very common on the white willow, but careful observation in many cases has shown me that they were visiting flowers and gathering nectar from trees not at all infested with plant-lice.

Page 322—On this page, Mr. Root gives an admirable illustration of that incomparable plant, the willow-herb. Curiously enough, in giving the scientific name he exchanges the generic and the specific names. The plant is known as *Eupatorium angustifolium*, and not, as he puts it, *Angustifolium eupatorium*. This plant is worthy of the good things he says of it. It is not only excellent for honey but has a most beautiful flower. This plant comes up thick over the burnt areas of northern Michigan, and so is often called fireweed. This name, like that of Indian-

pink, is unfortunate, as these names are also given to other plants which are very different.

Page 335—Is it true that dark honey is more unsuitable for wintering than other honey? If we give the definition for honey that some bee-keepers urge, that honey is the transformed nectar of flowers, then surely the above is not correct. It is true, however, that bees often gather nectar from bark-lice or scale-insect secretion, which I think they transform into honey. This is very dark and is certainly unfit for wintering. While I would not wish to use this latter in any climate where bees can not fly frequently, for purpose of winter food, I should not hesitate at all to use buckwheat or any other dark floral honey for winter food in the apiary.

Page 348—In his glossary, our author gives *Apis* as the family to which the bee belongs. This should have been the genus to which the bee belongs. It may be of interest to some of our bee-keepers for me to give the groups from first to last in succinct form, to which our pets of the hive belong. The phylum or branch, which used to be called *Articulata*, and which included worms, is now known as *Arthropoda*, a word meaning "jointed legs." All animals which belong to this phylum have not only jointed legs but also jointed bodies. Thus the sow-bug, crayfish or lobster, thousand-legged worm, and spider, as well as the insect, all belong to the phylum *Arthropoda*. The bee belongs to the class *Hexapoda*, or insects. The former name is given because they all, in the mature state, have six legs. They are called insects because their body is cut up into three well-marked portions, head, thorax and abdomen, besides the other rings and joints which make up these main divisions. Of course this class does not include the lobster class, with their varying number of legs, the eight-legged spiders, or the many-legged myriapods.

The bee belongs to the order *Hymenoptera*. This word comes from the Greek and means membranous wings. They are so called because they have thin wings like those of the common house-fly. This order does not include moths, butterflies, two-winged flies, beetles, bugs, locusts, etc. The family of the bee is *Apidae*, a word signifying honey-bee, as the typical genus is *Apis*. In this family, the larvae are always fed on pollen, and thus the bees are always provided with means for collecting this valuable food substance.

We have a great many bees, from the huge bumble and carpenter bees down to the small solitary bees which are often very beautiful. With very slight exception, none of the bees ever do any harm, and all of them will co-operate with the honey-bee in the valuable work of pollinating the flowers of our fruits and vegetables. The carpenter bees sometimes bore into cornices and window-casing of houses, but rarely do any serious mischief, and are easily dislodged by the use of a mixture of lard and kerosene oil. The genus of the honey-bee is *Apis*, and includes all those bees that have their hind legs bent for carrying pollen, and have no tibial spurs on these legs. The species of the honey-bee is *mellifera*. This includes all of the bees that have been domesticated, of which there are several races, as the Italian, Syrian, German or Black, Carniolan, etc.

In concluding these reviews of our three most important bee-books, I wish to say that the task has been altogether a pleasant one. There is so much to commend, so little to criticise. I am proud of our bee-books, and am proud of my brother authors.

Los Angeles Co., Calif.

A Celluloid Queen-Button is a very pretty thing for a bee-keeper or honey-seller to wear on his coat-lapel. It often serves to introduce the subject of honey, and frequently leads to a sale.

NOTE.—One reader writes: "I have every reason to believe that it would be a very good idea for every bee-keeper to wear one of the buttons as it will cause people to ask questions about the busy bee, and many a conversation thus started would wind up with the sale of more or less honey; at any rate it would give the bee-keeper a superior opportunity to enlighten many a person in regard to honey and bees."

The picture shown herewith is a reproduction of a motto queen-button that we have been furnishing to bee-keepers for a long time. It has a pin on the underside to fasten to the coat. Price, by mail, 6 cents each; two for 10 cents; or six for 25 cents. Send all orders to the office of the American Bee Journal.

The Premiums offered this week are well worth working for. Look at them.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

A Beginner's Questions.

My bees were put into winter quarters very light in stores, and I think they won't have enough to bring them thru till spring opens. I began feeding too late in the fall, and cold weather started in, so they did not have time to store much.

1. Can I feed them before good weather comes, or will I have to wait till good weather comes in the spring?
2. How large should the hive-entrance be in the spring of the year?
3. Will bees taken from a bee-tree in the woods swarm as much as tame bees do?
4. How much honey does it take to winter a colony of bees?
5. What time do bees generally begin swarming in the spring?
6. How can a person tell when the bees are to swarm?
7. Will bees taken from a tree store as much honey as a tame swarm?
8. How long does it take a new swarm to fill up the brood-chamber after they are hived, when there is lots of honey in the fields?
9. How many times should bees be allowed to swarm?
10. Should the entrance-guard be kept on when robber-bees are troublesome?
11. How long does it take bees to fill a super when there is lots of honey in the fields?
12. Where do the bees gather propolis?
13. Should bees have shade on a hot summer day?
14. Do bees need any salt in summer when they build comb?
15. How can I prevent second swarms?
16. Do bees store any nectar from corn, pumpkins and cucumber blossoms?
17. Will putting supers on a ten-frame hive prevent swarming?
18. Do the drones build comb and gather honey when newly hived?
19. Should the honey-board be on top of the frames, that is, between the super and the frames?

WISCONSIN.

ANSWERS.—1. If they have enough stores to last till that time, wait till weather when they are flying. But if you fear their starving before that time, don't wait; you may as well disturb to death as to let them starve to death. If you feed before they are flying, you must make sure they can get the feed. Hang a Doolittle feeder close to the cluster, or give them a brood-comb containing syrup, or give them candy right over the cluster.

2. No larger than in the winter, if as large. Anywhere from one to three square inches, according to the strength of the colony.

3. Fully as much.

4. It varies greatly; from 6 to 25 pounds or more. The size of the colony, the character of the winter, whether wintered in cellar or not, all have to do with the matter.

5. If wintered in the cellar, about the first day they are taken out. If wintered outdoors, perhaps about the last of March in Wisconsin. But these are hunger-swarms, or swarms because there is something wrong. Normal swarming for increase comes later in the North than in the South. In Wisconsin there may be rare cases in the last of May, June being as early as it generally begins.

6. By finding a number of queen-cells started in the hive. If a colony swarms the second time, it will generally be somewhere in the neighborhood of eight days after the first or prime swarm.

7. Just as much as another of the same strength. You will find the colony taken from the tree just as tame as any other.

8. That depends upon the size of the swarm and of the

hive, and the time of the swarm. It may be a week, and it may be not till the next year.

9. Once or less.

10. It will be a little help, but is not commonly used for that purpose. Strong colonies are a better guard against robbers.

11. It will be excellent work if done in two weeks. It may be less, but it is oftener a week more before all sections in the super are sealed.

12. From the buds and twigs of poplar and other trees.

13. It is desirable.

14. They seem to have a liking for salt, and a few bee-keepers take pains to furnish it to them. It perhaps has more relation to brood-rearing than comb-building.

15. Put the swarm on the old stand, and set the old colony close beside it, both facing in the same direction. A week later move the old colony to a new place.

16. Yes; much from pumpkins and vines of that sort, but mainly pollen from corn.

17. Yes, it will be an excellent plan if there are bees enough to fill them; but it may not prevent swarming.

18. I have never seen them engaged in such occupations when first hived.

19. That is the proper place for it if you use one; but honey-boards are not as generally used as formerly, except as queen-excluders.

Spring Questions.

1. I put into winter quarters an even 50 colonies, about $\frac{1}{2}$ Italians and the balance blacks. In the fall I ran them all together, made two rows, 12 in each row, back to back, and covered with gable roof like a house. From some cause my Italians went into the winter with less stores than the blacks, but I thought all had an abundance, and could have, I thought, taken two frames from each hive, but as it has turned out fortunately for them I did not do it.

Feb. 1st I put them all on the summer stands. At that time I thought they had plenty, but, for fear, I fed all the Italian colonies about five pounds of syrup each. Sunday, March 17th, as I was looking at them I noticed from my best Italian colony the bees crawling all around the front of the hive on the ground, and many dead bees. I got the smoker, looked into the hive and found they were starving—not one bit of honey. All my Italians are in the same fix, but not quite so bad as that one. The blacks are, most of them, able to get thru.

I at once began to feed, but I fear too late. What shall I do? We have had no winter, scarcely a day but what the bees have been flying. The peach-trees are all putting out in bloom yesterday and to-day; elm and soft maple are also in bloom, and the early wild flowers. Do you think the elm, maple and peach will provide food for them—that is, can they hold their own on that, or will they keep getting shorter of food?

2. Was it you that made a visit to Sebastian Co., Ark., some weeks ago? I have forgotten who it was. If you, kindly give me your impressions on bee-keeping and probable success in that portion of the country, as I live only 75 miles from Ft. Smith. The bee-papers give us very little information relating to our part of the country, in fact it's all for Northern bee-keepers.

3. Why have my Italians fallen behind the blacks? The Italians did store just enough honey to carry them thru (and it has turned out not enough to do that), while many of my blacks had from 1 to 2 supers of surplus. One early swarm of blacks stored 252 pounds surplus. I bought queens from several of the leading queen-breeders last year, but had very poor success with them. Does it take more stores to run them than blacks? or why is it they are all just ready to starve?

4. I want to clip all my queens. When would you do it—right now, or wait till they are stronger? As they now are, I can not open a hive but the robbers are right after me, and just cover the hive after putting in feed. I have to close it entirely up tight. I am nearly discouraged. Tell me what to do, and I will be so thankful.

INDIAN TERRITORY.

ANSWERS.—1. It is quite possible that the bees will be able to take care of themselves, but it will be well to make sure by giving some feed. In any case it will not be lost. You are fortunate in having weather when they can fly nearly every day, for that makes feeding an easy thing.

2. I have never been in that part of the country, and can give you no reliable information about it.

3. I don't know why the blacks should have done better

than the Italians. Possibly you have blacks that are unusually good and have been unfortunate in not having the best of Italians. More likely the treatment had something to do with it. The blacks were perhaps interfered with less than the others. If you changed their queens, etc., the Italians would not have so good a chance. As you had an open winter, the bees flying nearly every day, the bees would use more stores in winter, and it might be that the Italians were more active and used up their stores faster, but that would not account for the great difference in the amount stored last summer. There is room for considerable suspicion that the blacks had the better chance.

4. Try not to open hives unless absolutely necessary until time of robbing is over, when the bees will get enough to do on flowers that they will turn to honest pursuits. Certainly you should not clip till you can do so without danger from robbers. If for any purpose you are obliged to open hives, better do it toward evening; then there will be less danger of starting robbing, and if it should trouble a little, darkness will soon come to your relief.

A Dozen Questions.

1. The burning question with me is how to winter bees. This is the fourth year I have tried them in North Dakota, the second and third year I had heavy loss. This winter I have them in the same frame building. I have 11 hives closely packed together, and on top of each other, and covered with some wheat chaff. I gave no upward ventilation, left the honey-boards sealed down, put a wood tray two inches deep under each hive, and with wire-cloth on the entrance 2x3 inches. No ventilation on the bee-house ceiling, above the ceiling it is packed with chaff. The house is warmly built. I put an extra door on this winter, which gives two air spaces. I went in last week, and the thermometer was 29 degrees above zero. I could hear the low hum in all the hives I could reach.

2. Last season on account of the dry weather I got only about 70 pounds of surplus honey from the 3½ colonies, spring count, and in September when fixing them for winter I thought they had enough to tide over till spring. Two years ago I took your advice and sowed sweet clover; but for that, last season would have been a blank for honey. The past seasons I have kept down natural swarming by dividing, and extracting from the top hive. The coming season I would not seek more than one swarm from the strong colonies, and would like to know the best methods of dividing for increase. Guided by the American Bee Journal I have tried several ways, but had many failures. I seemed to lose at least time, honey, and sometimes bees. When is the best time to divide? and to manage the half that has no queen? Is there any need to destroy the extra queen-cells they make?

3. I sent South and got a good many young queens by mail; they all came in good order, and there were some fine queens among them. Several times I lost the queens by lack of care on my part, not looking out for the other queen in the hive. Now tell me how long they should be without a queen before they have one introduced?

4. In making a nucleus could I take a frame of brood with bees on it and introduce a young queen at the same time? or how many days after?

5. How far apart should nuclei be set to make it safe for a young queens to enter her own hive?

6. Do you think king-birds have anything to do with my queens getting lost sometimes?

7. Is there any danger of crowding too many bees into a hive? In September, when taking off the upper story, there were so many bees that they could scarcely all get into the lower hive. Would that hurt them in wintering? or would it be better to give some of the bees to a weak colony?

8. Is there any danger of killing the queen when you mix together bees of different colonies? How do you prevent it?

9. In taking a frame of brood and bees from a strong colony, to build up a weak one, will these bees be liable to kill the queen?

10. Would there be any danger in introducing a young queen to the part that is queenless, after dividing a strong colony? How long should it be before you give it one?

11. Would the bees receive a matured queen-cell as readily as a queen? How long should they be queenless?

12. In dividing a strong colony, how or where would you place the hives?

MINNESOTA.

ANSWERS.—1. It is possible you may have to give up the idea of wintering in that house. It is a hard thing on bees to be in a place where the thermometer stands at 29 degrees continuously. You may say it is much colder than that outdoors. So it is, but when a warm day comes the outdoor bees can have a flight, whereas your bees will not. It is questionable if you should leave the covers sealed down, but if there is a sufficient amount of warm packing over all it may do. The 2-inch tray under the hives is good, but it is not a good thing to fasten the bees in the hive with wire-cloth. When bees want to come out of the hive to die, they ought to have that privilege. You might find that they will winter better in the cellar under your dwelling. If it is impracticable to have them there, you could at least have a cellar several feet deep under the house in which to winter your bees, so as to raise the temperature to about 45 degrees. If you find them troubled with diarrhea, better get them out as soon as a day comes that is still, with the sun shining, and the thermometer 48 degrees in the shade.

2. If you want no more than one increase from each strong colony (and you are wise in desiring no more), it is possible that natural swarming would be the best thing for you. With that it is easy to prevent second swarms. If you divide artificially, do not begin before about the time of natural swarming. Generally there will be no need to destroy queen-cells. Perhaps the nucleus plan may suit you as well as any. Take a colony that is very strong and has a good queen if not as strong as you wish, make it so by giving brood in advance from other colonies—and take its queen with two combs of brood with adhering bees and put in an empty hive on a new stand. Seven to nine days later form nuclei, giving each one two or three frames of brood and bees from your queenless colony, and seeing that each one has two or three good queen-cells. If the queen-cells are at the outer edges of the combs, put them on the central surface, fastening them with a staple or nail. Put the hive with the old queen on the old stand, putting a nucleus in place of the queen. A week after forming the nuclei give each of them a frame of brood from the other colonies that have not been disturbed; a weak later still, one or two frames of brood; and so on till you have a full colony.

3. You may be successful by removing the queen at the same time you give the new one, providing the new one is not released too soon, but it is safer to have the new queen released four or five days after the removal of the old queen, and to make sure of this with the usual shipping-cage the old queen should be removed two or three days before the new one is put in the hive.

4. If the queen is caged, she should be put into the nucleus at the time it is formed. Two days after it is formed there would be little risk in giving the queen without caging. If the nucleus was formed with queenless bees—and generally it should be—then any kind of a queen, and especially a very young virgin, could be given at once without caging.

5. If there are no more than four of them they need not be apart at all. Two of them may be side by side, almost touching, with the other two facing the opposite direction, the two pairs standing back to back. Then another group of four may come with four feet of space between the two groups, and so on.

6. It may be.

7. Don't be afraid of too many.

8. Generally one of the queens will be saved, but it is well to take the precaution to kill a day or two in advance the queen of the bees to be united.

9. Not much danger unless you add nearly as many bees as were already in the weak colony.

10. If the queenless part is put on a new stand there would not be much danger after a day or two. But look out in taking bees from a queen and putting them on a new stand, that they do not desert the brood. It is safer always to form your nuclei of bees already queenless.

11. Generally a queen-cell will be received more readily than a queen. It will be a rare case that any colony will not receive a queen-cell 24 hours after being made queenless. This does not refer, however, to bees with laying workers; hard to get them to receive anything unless it be a virgin just out of the cell.

12. If you mean dividing into two parts—a thing that is of doubtful policy—you might set the two side by side on the old stand; then if one should get more bees than it should have you could move it away a few inches and bring up the other.

HOW TO BUY A \$100.00 SURREY

Follow Instructions Carefully

Take \$100, give your wife \$35.20 for pin money. Purchase a draft or money order for \$64.80 and mail it to us and we will ship you at once, our No. 232 Extension Top Surrey—the best Surrey ever sold anywhere for \$100, spot cash. The \$35.20 you give your wife represents the two extra profits you would have to pay in getting the job from a dealer. We

TWENTY MILLIONS IN GOLD

From Alaska during the year 1900.

Five millions of this came from the Nome district. Government officials estimate the output from the Nome district will be doubled the coming season. The Bluestone, Kougarak and Pilgrim rivers have been found very rich. There is hardly a creek from Port Clarence to Norton Sound in which the precious metal is not found, and hundreds of creeks unprospected. A rich strike has been made on the Yellow river, a tributary of the Kuskokwim.

GENERAL ITEMS

Early Spring in Arizona.

We are having an early spring. Alfalfa is about knee-high, and bees are gathering honey from fruit and desert flowers.

Today I found queen-cells started in all stages, from the egg to the sealed cell ready for swarming.

B. A. HOISELL, Jr.
Maricopa Co., Ariz., March 4.

Bees Wintered Well in Kansas.

I started last fall with eight colonies of bees, and they are coming thru the winter very nicely. I examined a few of them in February, and found some of the queens laying, and some brood in the larval state. The colonies are all on the summer stands. How is that for Kansas?

I love my bees, and am bound to give this country a fair trial before I give up trying to keep them here. I think the prospect will grow better when the farmers get to sowing more alfalfa.

I want to do all I can for the American Bee Journal, for I could not do without it now.

J. L. BADER.
Colley Co., Kans., March 10.

More Rain in Southern California—Sage Honey.

We have just had another nice rain, and the prospect for a honey crop in southern California is good, as most locations have had from 12 to 15 inches of rain to date. I have an apiary near Pasadena, where the rainfall has been 22 inches. There has been very little sage honey shipped from here during the past three years, but there will soon be some to ship.

FRANK McNAY.
Los Angeles Co., Calif., March 14.

A Voice from Southern California.

Having read with no small degree of amusement the comments and prophecies on the expectations and prospects of California's honey crop for 1901 and these not always given in the friendliest of terms, but tinged with a gleam of jealousy—I say so:

Now, fellow bee-keepers, honey-eaters, and friends who are hopeful and have a good wish for those who produce by the sweat of the brow and the pain of the bee-sting, that which of all others is one of Nature's choicest sweets, California has had a hard trial—especially southern California—in the three seasons of light rainfall just past, and perhaps no pursuit has been more severely tried, or suffered a greater percent of loss in proportion to the amount invested, than that of bee-keeping. And of the many who have “stayed it thru” almost all have had some other source of income, or turned at least a part of their attention to other pursuits, that they might save their bees until we should be blessed again with a normal rainfall that would justify them in giving their attention to the honey-producing industry. The editor of one of the leading bee-papers says: “We expect California will be wishing Colorado a ‘short crop.’” This is not a fair judgment of the temperament of us California bee-keepers, for I do not believe, at any time in the three trying seasons just past thru, that the bee-keepers of California wish to quit the effort at home and a failure on the fellow in another State.

Five years ago last fall I came to this part of the country from Oregon, and to amuse myself, the following winter I dug out from the hills and hived 24 colonies, and from these and subsequent purchases made with money earned by working out between times, I have built up an apiary of 164 colonies that are in excellent condition, and I have a few dollars

G. B. LEWIS COMPANY

WATERTOWN, WISCONSIN, U. S. A.

A HANDY TOOL-HOLDER!

Sent by Express, for \$1.50; or with the Bee Journal!
one year—both for \$2.00.

Every Manufacturer, Miller, Carpenter, Cabinet Maker, Machinist, Wheelwright and Quarryman, Farmer, or any one using a grindstone, should have one of these Tool-Holders. One boy can do the work of two persons, and grind much faster, easier and with perfect accuracy. Will hold any kind of tool, from the smallest chisel to a draw shave or ax. Extra attachment for sharpening scythe blades included in the above price. The work is done without wetting the hands or soiling the clothes, as the water flows from the operator. It can be attached to any size engine for hand or steam power, is always ready for use, nothing to get out of order, and is absolutely worth 100 times its cost. No farm is well-equipped unless it has a Tool-Holder. Pays for itself in a short time.

How to Use the Holder.

DIRECTIONS.—The Tool is fastened securely in the Holder by a set-screw and can be ground to any desired level by inserting the arm of the Holder into a higher or lower notch of the standard. While turning the crank with the right hand, the left rests on an steady the Holder; the Tool is moved to the right or left across the stone, or examined while grinding, as readily and in the same way as if held in the hands.

For grinding **Round-Edge Tools**, the holes in the standard are used instead of the notches.

YELLOW OR WHITE

Sweet Clover Seed

Free as a Premium

For Sending us One New Subscriber for a Year.

There has been so much written about both the white and the yellow variety of sweet clover, that we will simply say here that if one of our present regular subscribers will send us \$1 with a new name for this year, we will mail, postpaid, to the one sending the new name and the dollar, either one pound of yellow sweet clover seed, or two pounds of the white sweet clover. This is a good chance to get a start of both kinds of these honey clovers. Better send two new subscribers (with \$2.00) and get the three pounds of seed. Address.

Bees Wanted

10 or 15 colonies of Italian **BEES** on **LANG-STROTH FRAMES**. Address, H. KASZUSSEN, Oak Park, Ill. Box 151. 15A21 Mention the American Bee Journal.

"grand old man," Dr. C. C. Miller, who is so kind and obliging in telling us what we want to know. Some day we shall lose him, and his place will be hard to fill. May the Father above be good to the Doctor and his, is my prayer.

What would we better do with Mr. Hasty? He appears to be having a circus with us all. How would the editor like to go fishing with him, and afterward hear him tell how all the big 'uns got away—from the other fellow?

J. P. BLUNK.

Webster Co., Iowa, March 9.

[No, we don't know anything about fishing, so if Mr. Hasty wants a companion, on such a job, he'd better take Mr. Blunk, who is a diligent student of the late, lamented Izaak Walton.—EDITOR.]

Mistake in "Averaging Up."

On page 157, J. D. Gehring wonders "if J. G. Ginzels report of 14,000 pounds from 94 colonies is not a mistake." One thing is certain, as Mr. Gehring "figures it," his 170 pounds average is a huge mistake. Would not 140 pounds (nearly) reduce the cause for wonderment?

WM. WRAY.

Gratiot Co., Mich.

Queen-Button—Bees Wintered Poorly.

I think that little queen-button is the best thing out to advertise a bee-keeper, and I am sure that if every bee-keeper, old and young, male and female, would wear one of these little "catches" they would catch many a pound of honey which would otherwise remain packed away in the honey-room. When taking the last number of the American Bee Journal from the post-office, and glancing thru it to page 203, a bystander noticed the picture of the queen-button, and the first question he asked was, "Say, Mr. Golden, have you any honey?" Seeing that bee just put me in mind of the honey."

Some time ago I frequently spoke to our bee-keepers that was fearful that our bees would suffer greatly on account of the quality of winter stores and long confinement. Surely, my prediction is being fulfilled thruout this section, not because it has been so cold, but on account of the long confinement without a flight, and had winter stores.

J. A. GOLDEN.

Morgan Co., Ohio, April 1.

Wintered Well.

I wintered 25 colonies in chaff-packed hives, and up to this date they seem to be lively and doing well.

ALBERT BAXTER.

Muskegon Co., Mich., April 1.

Mistake in Mathematics.

In Mr. Gietz's article, on page 151, a little mistake in mathematics appears, and should be corrected without any offense being given, because mistakes—according to an old maxim—are no haystacks.

If a man is to carry 2,000 pounds of material, taking 50 pounds on a trip, to a place 500 yards distant, he will truly have to make 40 trips, but in going to and from the place of deposit he will have to walk 1,000 yards to complete his trip; therefore, the man carrying 50 pounds on a trip will cover a total of 40,000 yards, and the one carrying 100 pounds will walk one-half the distance, or 20,000 yards.

E. F. TRITTENBACH.

Northampton Co., Pa., March 11.

Experience in Getting Subscribers.

The editor has said from time to time that any one could get at least one new subscriber, but I have tried every man in this vicinity that keeps bees, and sent in 16 names at one time for sample copies, but not one would part with his dollar for subscription, but let his bees rot with foul brood, and then say, "Let them go; they don't gather any honey, anyway, so they might as well be dead as

alive." When you tell him that his bees are spreading foul brood among other apiaries, his reply is something like this: "Let them spread it; it won't do me any harm." I dare say you will have written by one of this class of bee-keepers, to help to get the foul-brood bill past, and they would be the ones to object if any inspector should come to examine their bees.

There is a good, honest farmer over south of us about three miles, who has nine colonies of bees in hives of all shapes and sizes. He was here this morning and left \$1.00 for the American Bee Journal. C. H. ALSTIN.

Hillsdale Co., Mich., March 18.

Short of Stores.

Bees in this community are short of stores, and the time is critical, but as peach-bloom is now on, with open and warm days, I hope they will pull thru without much loss.

T. SHIRLEY, M. D.
Pickens Co., S. C., March 29.

Report for 1900—Other Matters.

I have only a small apiary—from 40 to 50 colonies—and run exclusively for comb honey, as there is no market here for extracted. I depend upon the local market and orders by mail, all calling for comb honey. I disposed of 1,800 pounds of last season's crop in that way, at an average of about 13 cents per pound. Each case is marked with the net weight and grade, and in packing I am careful to have each section clean, properly filled, and as good, or a little better, than the outside exhibition sections. In that way I have secured a trade that takes all I can supply at outside prices. I enclose two, three and four cases in a light box or crate with hay cushion in the bottom, and ship by freight, unless ordered otherwise, mostly to points in North Dakota.

Last season was a fairly good one, my yield being 65 pounds of honey to the colony, and 50 percent increase.

I make all my own hives, sections, etc. The hives are 14x17x11 inches, inside measure, with 9 frames rabbetted to receive cover or super, also rabbetted top and bottom to fit. The bottom-board is fastened to the hive with three hooks, one in the middle of the back, and one on either side near the front. The cover is flat, having 2"x3/4" inch cleats nailed to it, the cover projecting slightly beyond the cleats. The entrance is 3/4" inch by width of hive, regulated by a triangular block to suit circumstances. I leave an inch hole near the top of the front end of the hive for winter ventilation, but close this up in summer.

I winter the bees in the cellar, and take them out when warm weather comes, without any regard to the season. I double all weak colonies, use honey-boards instead of cloth, removing them when placing in winter quarters. I raise the cover slightly and put on the honey-board, covering with newspaper, when placing on the summer stands, then replace the cover, making all tight and warm. I do not remove the paper until settled warm weather, and seldom lose a colony. I allow them to swarm naturally, and place the swarm on the old stand, moving the old one two feet, and allowing it two inches, and so on, until I move it to another stand. I usually give the new colony one frame containing some brood, placing it in the middle, and never have a swarm leave the new hive. I had one new colony that cast a swarm the eleventh day, and don't understand it. I make my brood-top-bars 1 1/2" inch, split with a saw to fit two inches, and the new bars are 1 1/2" inches, with little pieces-branded on the edge to serve as spacers. The bottom strip projects 1/4" inch beyond the ends to prevent the frame from touching the ends.

H. B. KNOWLES.
Winona Co., Minn., March 5.

pends upon the man—"the man behind the guns" wins the battle; the man behind the plow makes the crop—at the same time we can not expect as much work nor as good results from the man who is hampered by having to use inadequate tools as from the man who employs up-to-date methods and has an up-to-date equipment. Take the matter of farm wagons as an illustration. For years we used for farm work wagons with the old, narrow-tired high wheels. Every time we put a load on it we lifted about twice as high as there was any need of; every time we drove across a field we cut into the ground about twice as deep as was necessary; every time we started the horses we pulled them about twice as hard as the load required. Then some one hit on the idea of making a low-down handy wagon with wide-tired metal wheels, and the labor of farm hauling was reduced about one-half. The handy wagon became popular at once for all farm hauling. Every one who has used a low-down wagon is ready to say with the man in our illustration—"No more high wheels

"No more High Wheels for me, Neighbor."

for me!" We believe this is especially true of those who use the famous Electric Handy Wagon or the Electric Steel Wheels made by the Electric Wheel Co., at Quincy, Ill., who have been recognized as the leaders in this line of goods, and by their fair business methods and the high quality of their products, have made the name "Electric" stand for all that is excellent in wagon-making. They make metal wheels of all descriptions for wagons and implements of all kinds, and will sell either a wagon complete or a set of wheels for an old running gear. Very many farmers buy a set of low wheels for season the farm and set of high wheels for road hauling. The advantages of wide tires and low-down wagons have been so thoroughly discussed in the press and at institutes and clubs that there is no need of repeating them here. It has been demonstrated, time and again, that they mean easy loading and easy hauling; they save the man, they save the horses, they save the fields, for they do not "rut" nor "rip" up the ground as a narrow tire does. If you have not a low-down handy wagon we know that it will pay you to investigate. Send for the Electric Catalog. It's Free. It's poor economy to wear out your back or your hired-man's back when you get a better wagon, (and one that will last your lifetime, for less money than you pay for a high-wheeled laborer). Please mention the American Bee Journal when writing for a catalog.

GINSENG 81¢. In plants produce \$1,069.10 in 10 years. Grow in the Lakeland Ginseng Gardens, Amber, N. Y.
Please mention Bee Journal when writing.

Rocky Mountain Bee-Plant Seed!

(*Claytonia integrifolia*.)

...FREE AS A PREMIUM...

The ABC of Bee-culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to five feet in height, with large, large, clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this Cleome seed, and offer to mail it a pound package as a premium for sending as ONE NEW subscriber to the American Bee Journal, with \$1.00 or 1/2 pound by mail for 40 cents.

GEORGE W. YORK & CO.
118 Michigan St. CHICAGO, ILL.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Apr. 4.—Honey quotation remains the same as they have been for several weeks past. Stocks are very light and demand will more than take care of all that is on hand. Fair grades of white, 14¢ to 15¢; best ambers, 12¢ to 13¢; mixt colors, 10¢ to 11¢; buckwheat, 10¢ to 11¢; extracted, white, ranges from 7¢ to 8¢; amber, 6¢ to 7¢; buckwheat, 5¢ to 6¢. All of the extracted is covered by bids, but quality is the range of prices, the lowest figures in either of the colors applies to the sour, or off-flavored, and unripened. Beeswax, 3¢.

R. A. BURNETT & Co.

NEW YORK, March 19.—Our market is virtually bare of comb honey, and there is a fair demand for all grades. Fancy white is still selling readily at from 15¢ to 16¢; No. 1 white at from 13¢ to 14¢; amber at from 12¢ to 13¢; buckwheat, 10¢ to 11¢, according to quality and style of package.

As to extracted, the market is quiet and inactive, and a certain amount will have to be carried over again. Prices are declining somewhat, and if the honey is not made in large lots, concessions will have to be made. We quote: California white, 7¢ to 7 1/2¢; light amber, 6¢ to 7¢; other grades and Southern, 5¢ to 7 1/2¢ per gallon. Beeswax very firm at 28¢ to 29 1/2¢, and for exceptionally fine yellow, 29¢.

HILDRETH & SHELKENS.

BUFFALO, Apr. 4.—Fancy comb, 14¢ to 15¢; dark, etc., 8¢ to 12¢, as to grade. Demand moderate. Fancy beeswax, 27¢ to 28¢. BATTERSON & Co.

OMAHA, Mar. 30.—Demand fair; stocks light. Fancy white comb, 15¢ to 16¢. Extracted moving slowly at 7¢ to 8¢. We do not look for any particular change for the balance of the season, as present supply will just about be sufficient to supply the trade until new crop gets into market.

PEYCKE BROS.

DETROIT, Mar. 21.—Fancy white comb, 14¢ to 15¢; No. 1, 13¢ to 14¢; dark and amber, 10¢ to 12¢. Extracted, white, 6¢ to 7¢; amber and dark, 5¢ to 6¢. Beeswax, 27¢ to 28¢.

M. H. HUNT & SON.

CINCINNATI, March 21.—The demand for comb honey is nearly over, the stock of it also well cleaned up. Fancy white brings yet 16¢. Extracted is in demand at 7¢ to 8¢. For better grades bring 6¢ to 7¢; fancy white, clear from 8 1/2¢ to 9¢.

C. H. W. WEBER.

KANSAS CITY, Mar. 23.—Receipts light; demand normal at steady prices. Fancy white comb, 15¢ to 16¢; no amber on market. Extracted, 8¢ to 9¢. Beeswax scarce, steady demand, 25¢ to 30¢.

W. R. CROMWELL PRODUCE CO.

Successors to C. C. Clemons & Co.

ALBANY, N. Y., Apr. 6.—Honey market quiet. Light supply and light demand now. The stock is well cleaned out, so will be no old honey to carry over this season.

H. R. WRIGHT.

BOSTON, April 4.—Fancy No. 1 white in cartons, 17¢; A No. 1, 16¢; No. 1, 15¢ to 16¢, with a fairly good demand. Absolutely no call for dark honey this year. Extracted, white, 8¢ to 8 1/2¢; light amber, 7 1/2¢ to 8¢. Beeswax, 27¢.

BLAKE, SCOTT & LEE.

SAN FRANCISCO, Feb. 6.—White comb 13¢ to 14¢; amber, 11¢ to 12¢; dark, 10¢ to 11¢. Extracted, white, 7 1/2¢ to 8¢; light amber, 6 1/2¢ to 7 1/2¢; amber, 5 1/2¢ to 6 1/2¢. Beeswax, 26¢ to 28¢.

Considering the light output of honey last spring from California apiaries, present offerings are of tolerably liberal volume and are mostly of amber grades. The market is slow at the quotations. It is reported on good authority that California and ship from honey is practically dealt out in considerable quantity, which accounts in a great measure for the very limited business doing in the pure article.

CHAS. DADANT & SON, Hamilton, Hancock Co., Ill.

\$15.00 and \$25.00 Queens

Having a Measured Tongue Reach.

The call for queens of our celebrated \$200 imported mother has been so great that we have decided, in addition to the \$2.00, \$4.00, and \$6.00 grades of this stock, to offer some \$10.00, \$15.00, and even \$25.00 of this same blood. But these prices are for tested queens, the tongues of whose bees have been measured.

The \$10.00 queen is guaranteed to produce bees with a tongue-measurement of 19-100.

The \$15.00 queen, 20-100.

The \$25.00 queen, 21-100.

These last are very rare and with one exception this (21-100) is the longest tongue reach yet secured. We reserve the right, when we do not have the stock with the tongue reach called for, either to return the money or to send the next lower, remitting the balance. It would be well for our friends to put in their orders at once, and as soon as we get the grades we will send notice. When the money is sent, the queens will be forwarded. These will be put up in the very best manner possible; and while we guarantee safe arrival in good order to any point in the United States, on any railway line, we will not guarantee safe introduction. Such valuable queens should be released on hatching brood.

N. B.—It seems as if it ought not to be necessary to say that no one but a queen-breeder or a large honey-producer should order these high-priced queens; but it is a fact according to our experience that 1 beginners with only a few colonies will order our highest priced imported queens. Such bee-keepers have no more use for such queens than a pig has for a wheel-barrow.

FORTY-FIRST YEAR
No. 16

WEEKLY

MR. M. B. HOLMES,
Director of the Ontario Bee-Keepers' Association.
(see page 244.)

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & CO.

144 & 146 Erie St., Chicago, Ill.

Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

IMPORTANT NOTICES:

The Subscription Price of this journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, \$1.50 a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec'1" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

Reformed Spelling.—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "d" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

National Bee-Keepers' Association

OBJECTS:

To promote and protect the interests of its members.

To prevent the adulteration of honey.

To prosecute dishonest honey commission-men.

The Bee-Keeper's Guide:

Or, Manual of the Apiary.

—BY—

PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published today. Fully illustrated, and well written in the most fascinating style. The author is also too well-known to the whole bee-world to require any introduction. No bee-keeper is fully equipt, or his library complete, without *The Bee-Keepers' Guide*. This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers for the world of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two new subscribers—simply the Bee Journal for one year.

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street,

CHICAGO, ILL.

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers (with \$4.00.)

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation—"first come, first served"—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clipped, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

28 cents Cash paid for Beeswax.

This is a good time to send in your Beeswax. We are paying 28 cents a pound—CASH—for best yield.

low, upon its receipt, or 30 cents in trade. Impure wax not taken at any price. Address as follows, very plainly,

GEORGE W. YORK & CO., 144 & 146 Erie St., CHICAGO.

Best White Alfalfa or Basswood Extracted Honey

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are boxt.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

Address,

GEORGE W. YORK & CO., 144 & 146 Erie St., Chicago, Ill.

AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

THE OLDEST BEE-PAPER IN AMERICA

41st YEAR.

CHICAGO, ILL., APRIL 18, 1901.

No. 16.

* Editorial Comments. *

Are We Businesslike? is a question asked by Arthur C. Miller in the American Bee-Keeper. He thinks bee-keepers do not equip themselves in a way to do their work in the most economical manner. Too many try to make their own hives, or get along with a cheap bee-smoker. He says, "If the business is worthy of your attention at all, it is worthy the best tools and implements to do it with. Perhaps you can not spare the cash for many things needed; if not, then get the most important thing first, and the others as you can."

Freight Rate on Comb Honey.—On page 211 we called attention to the fact that the Western Classification Committee had before it a proposition to raise the freight rate on comb honey. We also urged that everybody interested should address a letter to Mr. J. T. Ripley, chairman of the Western Classification Committee, Room 604, Great Northern Building, Chicago, Ill., protesting against the proposed injustice. Among the responses to our editorial we have received the following from an Eastern commission firm:

BOSTON, April 6, 1901.

GEORGE W. YORK, & Co., Chicago, Ill.

Gentlemen:—We have noted with considerable interest your editorial on "Freight Rate on Comb Honey," in your issue of the 4th inst., and we heartily approve of the sentiment that you have expressed.

It seems to us that this matter should be gone into very thoroughly, and everything possible done to "head off" any such move on the part of the railroad.

It has always seemed to us a most unfair thing that there should be such a wide difference in the rate between honey in the comb and extracted honey. An example of this occurred in our own experience last fall. We found the rate on extracted to be \$1.10 per hundred pounds, from California to Boston, while on comb honey it was \$2.30 per hundred; and at the same time, in response to our question as to why a discrimination was made against the comb, the reply was, "owing to the extreme risk taken." Directly opposed to this was the fact that the railroad insisted that the goods be shipped at owner's risk.

Now, we quite fail to see why there should be any such great difference between the two classes as exists, when the comb is taken at owner's risk, thereby absolving the railroad from any responsibilities; and yet at the same time they seek to charge for it. It seems like the old case of trying to "eat the pudding and have it, too."

Would it not be a good plan for you to draw up and insert in your next issue a form of petition asking that all of your subscribers sign the same and send it to you, and your good self in return send it directly to the railroad committee?

A We suggest this as we have found invariably that united effort accomplishes more than spasmodic or divided. Whatever is every one's business surely ends up by being no one's, and we believe that by your wide and influential position much could be accomplished by you.

Yours for the cause,

BLAKE, SCOTT & LEE.

In reply to the foregoing most excellent letter, we would say that we had already sent in our protest, as strong as could make it. What is necessary now is, that all the honey commission firms and comb honey shippers everywhere shall simply pour in their letters vigorously protesting against the proposition to increase the present too-high freight-rate on comb honey. They should be mailed to Mr. Ripley as above directed.

What you should ask for is a rating of 1st Class—the present rating is 1½ times 1st Class. It should be lowered instead of raised.

The reasons we gave why lower rating should be made were these:

"The business will not stand such rates. In bulk and value honey compares favorably with 2d Class articles. Under the provision of

Rule 4, the carrier assumes no risk whatever for loss or damage. Covering the glass fronts, or packing in plain wooden boxes, would be no advantage, as the fact that the goods can be seen insures careful handling. Honey in plain wooden boxes will be thrown around roughly, the same as any other freight."

Other reasons will suggest themselves to our readers. Let us urge immediate action. Write at once—before you do another thing—if you wish to help prevent the enactment of an unjust ruling on the part of the railroads. Many protests coming from all sections of the country will have great weight with the Committee. Mr. Ripley will see that all are properly presented. Send them direct to him, and make them strong, but courteous.

Spraying During Bloom.—Green's Fruit-Grower is one of the leading authorities on the subject to which it is devoted. In the March issue it gives some excellent suggestions on spraying fruit-trees, and urges that it be not done while in bloom. Here is what it says, and every bee-keeper should not only read it carefully, but see to it that his neighbors read it—better get your local newspapers to copy it:

SHALL WE SPRAY TREES WHEN IN BLOSSOM?

In the coming time, to insure success in fruit-growing the fruit-grower will be obliged to manage his orchard in accord with scientific principles. Perhaps farmers with little scientific knowledge will be able to manage an acre or two so as to produce all the fruit required for home consumption; but to grow fruit for market so as to be able to compete with those who grow fine, first-class fruit, he will be obliged to know enough of entomology to know what poisons to use to destroy the different species of insects, and also when to apply those poisons to effect greatest results, and at the same time do the least harm to the trees or fruits. He will also need to know enough of fungology to be able to combat the different kinds with remedies, when those remedies will be most effectual. As it happens, most of the insect enemies come into active life with the first warm days of spring. A few warm days will hatch the eggs in which the insects have past the winter, or cause the larvae, which have spent the winter in pupae, to leave their winter abodes and commence crawling over the tree or plant on which they have wintered, in search of the tender leaves, which form their most appropriate food. The instinct of the maternal parent guides her to deposit her eggs close to suitable food for the young larva. Hence we learn that some of the most formidable insect enemies of the fruit culturist—the bud-worm, the case-bearer, the apple-leaf folder, the leaf-crumpler, and several others a little less destructive, are ready to enter the opening bud and commence eating before it is fully expanded, and those very formidable enemies, the tent-caterpillar and the canker-worm, soon follow. There is no period in the life of those insects when they can be so easily destroyed by arsenical poisons as when they first begin to feed. A weak mixture of arsenic will then destroy them while a much stronger mixture may fail to do so when they have attained to larger growth. It is evident, then, that apple-trees should be sprayed with Paris green, or other forms of arsenic, when the buds are first beginning to swell, or when the leaves begin to unfold. As many kinds of fungi commence to grow with the first warm days of spring, Bordeaux mixture can be profitably mixed with the arsenical poison.

A few years ago, from a mistaken idea of the time when the codling-moth first lays her eggs, orchardists, fearful that if they waited until the apple-blossoms fell it would be too late to destroy the larvae, sprayed their trees while in blossom, and bee-keepers complained that their bees were poisoned, and prevailed upon our Legislature to pass a law forbidding spraying while trees are in blossom. Many orchardists felt greatly aggrieved by this law, asserting that they were forbidden to spray just when spraying would do the most good, and that they must sacrifice their apple-crop upon their own land, for the benefit of the bee-keeper who had no claim upon their orchard as a bee-pasture. More recently, a careful observation of the habits of the codling moth led to the discovery that she does not deposit her eggs immediately after the blossom falls, but several days later, and that instead of starting them in the calyx, or blossom end of the fruit, as had always been supposed, she lays them upon the side of the young apple, clinging them to the rind, and that when the eggs hatch the larvae crawl over the fruit in search of a place of concealment, which they generally find in the partially closed calyx. This goes to show that there is no occasion for haste in spraying immediately after the blossoms fall, but

that any time before the calyx closes will answer, when the little cup may be filled with the poisoned water ready to give the worm an inhospitable welcome to its first meal.

Still more recent investigations show that it is not only not necessary to spray for the colling-worm when the trees are in blossom, but that it is a positive detriment to the fruit to spray at such a time. At the late meeting of the Western New York Horticultural Society, Prof. S. A. Beach, of the New York State Experiment Station at Geneva, detailed some experiments he had made in spraying apple-trees, when in bloom, with Paris green. He experimented in two orchards in Ontario County, and two in Niagara County. Had sprayed some trees in all of the orchards and left others contiguous without spraying. All the trees were full of blossoms. On the trees sprayed, but few apples set, a very large proportion of the blossoms falling, apparently, before the fruit set in, while on those not sprayed a very large crop of fruit grew. To make the test still more conclusive, he selected trees very full of blossoms alike on both sides, and sprayed one side of each tree, leaving the other side unsprayed. The result was, on those sides sprayed, the fruit set very sparsely, while on the opposite side, not sprayed, a heavy burden of fruit grew. Prof. Beach came to the conclusion that where you fairly hit an apple blossom with Paris green strong enough to kill insects, you will pretty certainly kill the blossom. The organs of reproduction in fruit-blossoms, when fully exposed, are very tender and easily killed. A slight frost, or a long, cold rain, will often leave an orchard covered with blossoms, with little or no fruit. If these experiments shall be confirmed we shall confess that the Legislature "bumbled better than it knew;" that while protecting the lives of the bees it prevented fruit-growers from destroying their fruit.

The foregoing would seem to annihilate the dangerous advice given by a certain manufacturer of spraying outfits who advises—yes, urges—fruit-growers to spray while their trees are in full bloom. The fruit-growers and bee-keepers should in some way unite in order to prevent the spreading of such harmful instructions as to the spraying of fruit-trees, and do all in their power to have the quoted paragraphs from Green's Fruit-Grower given a wide reading. It is not only in the interest of bee-keepers, but as much for the benefit of the fruit-growers themselves. There should be unity of effort between these two classes of people in order that each may win the best results.

Beginning Bee-Keeping.—We have lately received quite a number of letters from people who are contemplating embarking in the bee-business. And the questions they are asking are simply bewildering to a busy man.

Now, we don't object to being helpful along the line of furnishing all the information we possibly can to all enquirers, but we must be allowed to object when it comes to expecting us to sit down and copy out several times a day all that is found in the "ABC of Bee-Culture," "Langstroth on the Honey-Bee," and "The Bee-Keepers' Guide." The best we can do is to advise the purchase of one or all of those three books, in connection with a year's subscription to the American Bee Journal, and then let "the other fellow" sit down and "drink in" all he wants.

Every one who intends keeping bees should first get a good supply of the best bee-literature to be had, and thus be able to answer many of his own questions. Self-help is the best help. Each should by his own efforts inform himself as far as possible, then when he has exhausted his own resources, call upon others. First get and read a good bee-book thoroly, then get the bees. Then read your book again. Then you will be ready for a good bee-paper, and, very likely—more bees.

Finding Queens is frequently a very difficult and annoying procedure. Mr. D. H. Coggsball's method is thus described in the Bee-Keepers' Review:

"Fill a hive with empty combs, set it upon the stand of the colony containing the queen that is to be found, setting the colony to one side. Put a queen-excluding honey-board upon the top of that. Now take the combs, one at a time, from the colony, and shake the bees into the empty hive. The bees will at once run down upon the empty combs below, and the queen is easily found upon the top of the queen-excluding honey-board."

Sowing Cloome Seed—We have had several enquiries as to the sowing and growing of cloome, or Rocky Mountain bee-plant. Will some one of our readers who has had experience with this plant, kindly furnish the information asked for, especially giving the time of sowing, the preparation of the ground, etc.? Does it grow on dry or wet land, and in what part of the season does it bloom? Does frost kill it when it is young? We shall be pleased to publish an article covering all the points in connection with this subject.

The Premiums offered this week are well worth working for. Look at them.

* The Weekly Budget. *

MR. J. C. WALLENMEYER has been engaged to conduct the apian department of the Poultry, Bee and Fruit Journal.

MR. C. P. DADANT was in attendance at the meeting of the Chicago Bee-Keepers' Association, held April 4th. It was one of the most successful meetings, both in numbers and interest, that the Association has yet had. And very much was due to the presence of Mr. Dadant. All united in the hope that he will come again.

PROF. J. C. YORK, principal of the high school at Girard, Ohio, writing us March 26th, said:

"I want to congratulate you upon the skill and taste you have displayed in adding improvement to improvement in the American Bee Journal. Really, it seems to me as much superior to the Journal of 1885 as the new Deering self-binders are superior to the old low-down that were in use about 18 years ago. I enjoy 'The Home Circle.'"

STENOG is accustomed to begin his department of "Pickings from Our Neighbors' Fields" in Gleanings in Bee-Culture with an original rhymical stanza. Lately he had this:

"Don't kill the pretty bumble-bees
That hum around the barn;
They'll bring the price of clover down,
But ne'er a person harm."

Stenog certainly must have been sleeping in the barn on a cold night and suffered much harm from it, or he wouldn't be guilty of trying to make "barn" and "harm" rhyme. Now, if he'd had the bees humming around the farm it would have been all right—his stanza would have been less harmed.

We used to try to compose poetry, but it usually turned out to be such decomposed stuff that we long since have discontinued our efforts in that line. Shouldn't wonder if Stenog would soon follow our good example, unless he reforms, and treats the King's English more kindly than in the sample quoted above.

MR. M. B. HOLMES, of Ontario, Canada, is presented on our first page this week. Those of our readers who were present at the Buffalo convention in August, 1897, will recognize it as the picture of the eminent Canadian who contributed the valuable paper at that gathering, on "The Progress of Bee-Keeping in Canada."

Mr. Holmes, for many years, has been connected with the Ontario Bee-Keepers' Association, and that he enjoys the confidence and respect of the members of that great organization is proven by the fact that he has at times held the highest positions of honor within the gift of the Association. He takes a deep interest in all matters pertaining to bee-keepers, and readily responds to the demand of any project which will forward the interest of our industry.

The Ontario Bee-Keepers' Association made an exhibit of 40 tons of honey at the Colonial and Indian Exhibition in London, England, in 1886. Mr. Holmes' contribution to this exhibit being one and one-fourth tons.

Until a few years ago Mr. Holmes resided on his fine farm, but finding it not to be a very good place for a constitution not always the best, he rented his beautiful country home, and purchased a commodious brick residence in the beautiful and thriving village where he now resides, and has plenty of leisure time. He commenced bee-keeping in 1881.

It is always a pleasure to us to present to our readers portraits of the prominent bee-keepers among our Canadian "cousins." They have some of the very best representatives of our pursuit over there. We shall never forget attending the National Convention held at Toronto, in 1895, where it was our good fortune to meet many of their number, such as J. B. Hall, Wm. McEvoy, R. McKnight, F. A. Gemmill, etc. They are all wide awake, and take a great interest in everything pertaining to the apicultural business.

On another page of this issue will be found the paper read by Mr. Holmes at the last meeting of the Ontario Bee-Keepers' Association.

Contributed Articles.

Saving Section-Combs From Foul-Broody Colonies.

BY WILLIAM McEVON.

LAST fall foul brood started in one of my out-apiaries. I had the affected colonies removed out of reach of the other bees, and then burned the brood-frames and the hives. My apiaries are arranged for comb-honey production, and at the close of the season the supers from all the apiaries were brought in, and thru mistake those from the diseased apiary were piled in with the others, and now I don't know the one from the other.

I find that I have about 200 supers full of sections which contain empty combs, and combs partly filled with honey. Will you kindly tell me if these supers, just as they have been taken off the hive, and ready for use, can be safely used the coming season without spreading the disease?—ILLINOIS, U. S.

In the honey season bees store honey in cells where foul-brood matter has dried down, just the same as they do in other empty cells, and when the bees, in making room for brood in times of honey-flows remove the unsealed honey out of the diseased cells to cells partly filled with good honey in the sections above, it will disease it at once.

If you had extracted the honey out of those sections and then placed them back on the foul-broody colonies, and left them there until the bees lick them out clean and dry, that would have made them perfectly safe to use on any colony of bees. But as the case now stands, you can not place the sections that contain honey on your brood-chambers without spreading the disease, because some of the sections that were taken off the foul-broody colonies will have a little of the diseased honey in them, and the bees will feed some of it direct to the larvæ as soon as you put them on.

It costs you something to buy these sections, and comb foundation, and it took some time to put the foundation into over 5,000 sections, and your bees added many dollars to their value when they drew out so much foundation into nice combs, and if you had to destroy the 200 supers and their contents (to be safe), it would be a serious loss to you. You don't need to destroy anything if you treat as follows:

Take every section that has *any* honey in it, out of the supers, and bring them into a warm room, run the temperature up above summer heat, and leave them there until you can extract the honey out of them easily, then *extract the honey out of every section, and after you have done this put all of these sections into supers by themselves.* Then put frames with comb foundation starters, into empty hives, and on these place queen-excluders and the *extracted sections*, and in the honey season hive your swarms in these prepared empty hives with the extracted sections on where you will get them filled up and finish in the shortest possible time.

All the sections that you have with *clean, dry combs* in are perfectly safe to use on any of your old hives of bees. When the robbing season is over, and your bees are working nicely in fruit-bloom, take the combs out of the brood-chambers (in the apiary that was diseased), and hold them so the sun can shine into the bottom of the cells, and very carefully look for stain marks of foul brood on the lower side and bottom of the cells. Foul-brood matter glues itself fast to the lower side and bottom of the cells when it is drying down, and there it will remain just as long as the comb lasts, and *such combs can not be made safe to use, but it is entirely different with clean, new, white combs that never had any brood in*—they are perfectly safe to use on any colony of bees after they have been licked out by the bees until they are *clean and dry.*

If you find a few cells with the stain marks of foul brood in any of your colonies (a thing you might easily overlook), treat such colonies during the honey-flow, but don't waste any time on empty hives that foul brood has been in, because they can not disease any colony of bees.

Woodburn, Ont., Canada.

Producing Extracted Honey—Getting More of It.

BY C. DAVENPORT.

IN order to understand how more surplus extracted honey, with less work and less swarming, can be secured here by the method I am about to describe, if only eight frames are allowed for a brood-nest, than can be when a

larger number are used, it will be necessary for me briefly to describe a few things in regard to my locality, the most important of which is that in the spring, after the weather becomes warm enough for brood-rearing to progress rapidly, there is but a short time, comparatively, until the white harvest commences. Eight frames are all or more than 90 percent of the queens can keep full of brood and eggs before clover bloom; afterwards thru June, July and August, a larger number of combs, if the queens are allowed access to them, will be kept full of brood. But before this extra brood matures into field-bees, the battle has already been fought—like Blucher at Waterloo, they appear too late.

In a locality where the weather, or the time of the main flow, is such that a young queen can occupy a larger number of frames in time so that the brood will mature into field-bees to be of service during the harvest, it would, without any question, pay to use a larger brood-chamber. Usually here there is enough gathered from early spring until clover bloom to keep brood-rearing up. Strong colonies often secure more than they can use for this purpose, but what is gathered before clover is dark and hardly fit for table use. Now, with strong colonies run for extracted honey, instead of putting on the regular full-depth extracting combs, a set of shallow frames is given them to store this dark spring honey in, and what they do not use for brood-rearing is all put in them, for they enter and occupy these shallow combs almost as soon as they are placed on the hives. Often when the white flow commences these strong colonies will have hardly a pound of honey in the brood-frames, tho the super of shallow combs may be nearly full. But, as I have said, this is dark honey, and if it was in the regular extracting frames it would have to be extracted, or the first extracting of choice white clover honey would be so badly colored by it that it would not sell for much if any more than half what pure clover would bring.

Now note this: By using this super of shallow combs, we save one extracting, and keep the brood-nest bare of stores. Here, just at or soon after, the commencement of the main flow is the time strong colonies prepare to swarm, but when we remove this super containing all their stores, a full-depth story of empty combs is given. Zinc is placed between the two stories, two or three of the frames containing the most hatching brood are placed in the upper story, and a like number of empty combs from the upper story are placed in the center of the brood-nest below. A colony so treated will, with me, seldom offer to swarm, no matter how good the season is, provided they are given plenty of drawn comb to store all the nectar they can gather, for there is practically no honey in the brood-chamber at any time during the swarming season.

With 10-frame hives the case is different; the queen, as I have explained, can not occupy more than eight of these frames, and the unoccupied space will always be filled with honey before the bees will store any in shallow frames overhead, and honey in the brood-chamber is a great factor to induce swarming. The frames containing the most honey can, of course, be removed to the upper story at the time it is set on. I have often done this, but it does not have the check on swarming that the entire removal of all stores does. But I have found that with these 10-frame hives, even if the combs containing the most honey are entirely removed, swarming is more apt to occur than with 8 frames, for the reason that with 10 frames, storage in the brood-chamber is more apt to be commenced, or rather continued, and when once started it is apt to be kept up until the queen becomes crowded, then swarming is the natural outcome. Even when two full-depth stories are allowed for a brood-chamber, I have often found that the queen would become crowded enough to induce swarming unless a close watch was kept.

If one has time during the main flow to overhaul and extract from these large brood-chambers, swarming can largely be prevented, or if 3 or 4 stories are used, and the queen is allowed access to all of them, but little swarming will take place. But when we come to extract from such at the end of the flow, the amount of surplus found after overhauling the whole outfit will be disappointing if compared with what is secured from colonies whose queens are confined to eight or ten frames.

By the use of these half-depth stories, I have been able to overcome most of the difficulties I found about producing extracted honey in a large way, first in regard to this dark surplus gathered in the spring. When the regular full-depth extracting frames were set on first, most of them had to be extracted before the white flow and with a large

number of colonies this would mean a good deal of work at a time when other important work connected with my regular business of producing comb honey needed to be done; and, besides, after extracting this dark honey there would enough remain in the combs to shade the first extracting of white honey so it would not be first-class. Then when the queens are confined to eight or ten frames I found that these colonies would almost always be too light in stores for winter, so that a good deal of feeding was necessary; but with the shallow frames I am able also largely to overcome the work of this, for my practice is to set these supers at the time they are removed, on colonies that are to be run for comb honey, then as soon as they get well started to storing in them, they are raised up and a super containing sections is put on next to the brood-chamber; by the time a second super is required the one containing the extracting frames is stored in the honey-house until after the white flow, when they are again, if not already full, placed on the colonies being run for extracted honey, in order to have them all filled solid during the fall flow. Then all the work about feeding these light colonies is to set on a super containing as many of these filled combs as seems necessary, and from experiments with feeding in this and a similar way with unfinished sections, I believe a colony will winter in a cellar kept at a temperature of 45 or 50 degrees just as well with their stores in a super as they will if they are in the combs of the brood-chamber.

Last spring I set some of these supers containing honey in the honey-house as soon as they were removed from the extracting colonies, the fore part of the season—but little of this was sealed, but it kept without granulating or souring until the commencement of the fall flow.

The only trouble I have about this plan is that moths are liable to damage these shallow combs greatly during the time they are stored. In some manner the moth-eggs get in the combs while they are on the hives. Bi-sulphide of carbon will overcome this with but little work or expense, provided there enough of its deadly fumes does not remain in the honey to make it unfit for winter stores. I expect to know something definite in regard to this soon, for last fall I subjected all the winter stores of five colonies to its fumes for four hours, which is longer than is necessary to kill moth-worms and destroy the vitality of the eggs that may be in the combs at the time they are treated.

Southern Minnesota.

No. 2.—Drone-Bees and Their Utility.

Can We, and Shall We, Control their Production?

BY C. P. DADANT.

WE have seen in a former article, why Nature has decreed the rearing of so many drones in each hive. It is in order that each young queen may readily find a mate at her first bridal flight. We now will consider why some colonies build more drone-comb than others.

When a queen is young and healthy she lays plenty of worker-eggs and seems to prefer it, so if there is any understanding between the queen and her bees, the bees will, to please her, build most worker-comb. Thus a new swarm, with a strong and healthy young queen, will usually begin by building all worker-combs. But if there is a lull in the crop and some of the brood hatches out of the comb already built, the queen will have plenty of room ahead, and the few remaining combs will be drone-comb whenever they are built. For the queen prefers the worker-comb, we must take notice that the workers prefer to build drone-comb, for it is more quickly built and is just as good as the other to contain honey. It is evidently for this reason as well as because they feel the need of drones, that a queenless colony will build almost nothing but drone-comb. If we supply a new swarm with a large quantity of worker-comb already built, saved from diseased colonies of the previous winter, and give this swarm only one or two empty frames, the result will almost invariably be drone-comb in those frames, for the queen has plenty of room to lay and the bees do not see the need of worker-cells.

In the same manner, if the crop is already well on, and the queen is getting tired of incessant laying of worker-eggs, and seeks for drone-cells as a rest, all or most of the comb built will be drone-comb. In such instances a much greater proportion of drone-comb will be built. In early

spring, before the bees have begun the busy season, and the hive is only partly full of brood, if at that time we remove a central comb, and replace it with an empty frame in the middle of the brood-nest, in nine cases out of ten the comb will be of worker-cells, because the queen needs worker-cells in this warm spot, even tho there may be plenty of worker-cells unoccupied at the outer edges of the brood-nest but too cold for her to reach. But if the same thing is done in the warmth of the honey crop, the result will be the reverse. In the statement of the foregoing conditions I do not wish to be understood as laying an iron rule. The actions of the bees are subject to many varying influences, and results are not always what may be expected, but the propositions above will prove correct in most instances. So if we wish to have the greatest possible amount of worker-comb built by the bees, without using comb foundation as a guide, we must, as uniformly as practicable, have the combs built by natural swarms with young queens, and these swarms must not be supplied with a portion of their combs already built. In short, we must either supply the swarm with all combs built or with none.

Since the number of drone-cells in a hive depends very much upon the conditions of the swarm at the time that the combs were built, it is still more difficult to give an approximate idea of the number of drones that will be reared in an average season by an average colony. By looking thru a number of works on apiculture, I find that the proportion of drones to worker-bees, in the swarming season, has been variously estimated from one-tenth to one-thirtieth. There is no doubt that it varies a great deal. There is no doubt also that the difference in results is in favor of the colony containing few drones, and yet Cheshire calls our attention to the fact that it is the colonies that rear the most drones which have the best chances of self-reproduction, since not only their queen stands a better chance of mating, but the queens of other colonies are also more likely to mate with drones of the most prolific colony, as they are most numerous. Is it advisable for us to control the production of drones in a hive?

Is the drone in the hive of use for other purposes than for the fertilization of young queens? Are the drones of one colony as good for breeding purposes as those of any other colony? If we decide upon the necessity of controlling the drones, is it best to destroy them after they are hatched, or while they are hatching, or is it best to prevent their production?

The first two of these questions would better be considered together, for it is the greater or less usefulness of the drones which will cause us to decide whether it is desirable to control their numbers. It has been asserted over and over again, that the drone is needed in numbers not only to supply mates, readily found, for the young queen, but also to keep the brood warm in spring. Dzierzon and his English translator, Abbott, disagree on this subject. Dzierzon says: "The sole purpose of the drones is to fertilize the young queens. As in the vegetable kingdom, pollen, on the male part of the flower, is produced in abundance, so does Nature produce an abundance of males in a colony of bees, in order that the queen, upon which the well-being of the colony depends, may be fertilized the sooner. It is obvious that drones were not also intended to produce heat in the hive, as has often been attributed to them, for when the young queen has been successfully fertilized and begun to lay eggs, which perhaps at the same time cool weather sets in, at this very time, when the temperature in the hive would require to be raised, the drones are driven out as being no longer useful."

His translator, Abbott, says in regard to this: "We can not accede to the author's assertion that the fertilization of queens is the sole purpose of drones' existence. It is well known that when a swarm has left the hive there is often but a handful of worker-bees left at home to care for the huge mass of brood in all stages, that the hive contains, and should a cold night follow a swarming day, as is often the case, this handful of workers would find it impossible to maintain the necessary heat in the hive, and there would be great loss of brood and bee-life."

Evidently neither of these writers lays any value upon the drone as a warmth-producer at the beginning or the end of a season, and with good cause, for, in order that the drone should produce heat, it is necessary that he himself should be reared with expenditure of both labor and heat on the part of the worker-bees at a time when they are not numerous. And if in the place of, say 2,000 drones, we should secure the same space of worker-brood, say 3,000 worker-bees, it is clear that they will not require any more

heat to be produced, and will in their turn produce as much as the drones would have furnished. Therefore, the only contention between the two writers, that needs any consideration, is whether or not the drones that remain after a colony has cast a swarm are of more use in keeping the hive warm than workers would be.

The contention of Abbott is that if they had been workers, they would have gone with the swarm, while being drones they stay in the hive. This is not altogether correct, for a colony with many drones shows many drones in its swarm. But perhaps more of them return home than of the workers. Yet, Dzierzon, we must remember, is a great observer; he it was who discovered parthenogenesis in the queen-bee and we must be sure that he does not make statements without good cause, but perhaps the difference in observations comes from the difference in location. Dzierzon experimented in Germany, while Abbott experimented in England, and there is but little doubt that the summer nights are cooler in England than in Germany, so this would explain Abbott's regard for the possible use of the drones in keeping the brood warm for a day or two after the casting of the swarm. I say a day or two, because we all know that at that time the bees are constantly hatching in great numbers, and it takes only a short time to recuperate the loss enough to keep the hive warm. In a colony that swarms, the daily hatch of worker-bees is between two and three thousand, sometimes more, and but little time is needed to recuperate the strength of the colony so as to enable it to take care of itself. Then let us suppose a colony with a minimum of drones. Is it very likely that this colony will actually suffer? Are such instances on record? And in domesticity, is it not entirely practicable for the apiarist, if a hive is left too bare of its bees, by the swarm, to mend this defect by returning a number of the bees to the old hive, after the swarm is hived? Surely, this one item of a possible use of thousand of idlers for a day or two for the sake of warmth, is not sufficient to justify their presence. They are the very ones that help induce the bees to swarm early, by their noise every warm day, and by their encumbering presence on the combs at all other times.

So my conclusion would be that we should give but little attention to the possible use of drones for any but fertilizing purposes. If we can avoid the breeding of them, we must surely be well repaid by the additional number of workers that we can rear in their stead.

I will next consider the different methods of getting rid of the drones, or of preventing their being produced, and of making a selection of them for breeding purposes.

To be continued.)

Mediterranean Flour-Moth Infesting Honey-Combs.

BY PROF. C. P. GILLETTE.

IN the American Bee Journal for March 29, 1900, under the caption, "No Wax-moth in Colorado," I said:

"But there is a smaller moth that is generally distributed over the country, commonly known as the Mediterranean flour-moth, which I have repeatedly seen infesting honey-combs. The larvæ of this insect

FIG. 2.—FRAME OF HONEYCOMB SHOWING COCOONS OF MEDITERRANEAN FLOUR-MOTH.

do not seem to care for wax or honey, but feed upon pollen, and perhaps propolis as well...and I have seen them in crated sections of comb honey."

I do not wish to change a word of the short item referred to, but as some fear that my statements might lead a careless reader to think that this insect is common in crated sections of honey from Colorado, I should like to say further that such is not at all the case. As stated above, this insect seems to care only for pollen, and possibly propolis, but not for wax or honey. I do not suppose it would ever be found in sections of crated honey except where the sections are kept for a time in the same building or room with old honey-combs that are infested with this insect. It is only in two or three cases of this sort that I have seen the larvæ on sections of comb honey in sections. On one occasion I saw them in considerable numbers over a small number of sections, and on some of the sections they seemed to be feeding upon propolis which the bees had deposited in the corners in considerable quantity.

So this insect would only be of rare occurrence, at most, in section honey, and could no more be looked for from Colorado than from other States, as it is a generally distributed and a well-known pest in flouring mills in this country.

To enable bee-keepers to recognize this insect and distinguish it from the old "wax-moth," I will refer them to the accompanying illustration (Fig. 1) from Insect Life, Vol. II, U. S. Dep. of Agr. The moth is shown at *a* and *b*, the larvæ at *c* and at the extreme right, and the pupa or chrysalis at *d*—all enlarged. The lines at the sides of the figures give the real lengths.

That these larvæ can infest old combs badly is illustrated in the reproduction of a photograph of a frame of old comb that is nearly covered with their cocoons, shown at Fig. 2. This engraving is from Bulletin 47 of the Colorado Experiment Station.

Larimer Co., Colo.

Queens—The Best None Too Good.

Read at the convention of the Ontario Bee-Keepers' Association at Niagara Falls, in December, 1900.

BY M. B. HOLMES.

AS stated in the program of this convention, I am to give an address on the subject of "Queens" and it may be presumed that the punster, as he scans the list, will see his opportunity. If he be a sporting man he will at once suggest "The Queen of the Turf;" or if he be a society man his thoughts will immediately become centered on "The queen of the party," force of habit and influence of association acting as a matter of course, as the prompter behind the scene in these and other similar flights of fun and fancy.

To this class of individuals, if such there be present, I have only to say, that this Association of practical men has convened in this city for purely practical purposes; that it is composed of individuals who are not speculative

FIG. 1. MEDITERRANEAN FLOUR-MOTH.

merely, but operative in the strictest sense of the term; and that the only queens eligible for consideration at *this stage* of this regularly organized meeting of Canadian and American bee-keepers, are the queens of our colonies, and mothers of our most wonderful pets—the honey-bees.

The practical man, contemplating the advisability of entering upon any line of work or business, carefully studies the situation from every point of view, and when fully convinced of its desirability as a lucrative venture, complies most assiduously with all the conditions necessary to the complete success of the undertaking.

That all business men are not thus thoro in calculation and execution, goes without saying, and it is also perhaps safe to infer that bee-keepers as a class are not without their failings as well.

But every bee-keeper knows, or thinks he knows, all about queens, and yet it would seem as if some—perhaps too many—bee-keepers are satisfied by merely knowing that a *queen* is in the hive, without any consideration as to her qualifications or ability for the duty which she is to perform.

The splendid hives and comb foundations of the day are certainly a boon which every true bee-keeper appreciates, but the great center on which success most largely depends—that "center" at which no "master" bee-keeper can err—is in securing "the good queen" for every colony.

What do I mean by "the good queen?" By the use of the term "good queen" I mean the queen that will do the largest amount of work in a given time.

The late Lorenzo Lorain Langstroth, who has been justly styled the Father of American Apiculture, describes a good queen in that marvelous work of his on "The Honey-Bee," as one that will lay 3,500 eggs per day for several weeks in succession during the breeding season.

What bee-keeper of any considerable experience has not had occasion to note the difference between good, medium, and poor queens? The colony with but a handful of bees, so to speak, gaining so rapidly in numerical strength as in some cases to exceed the more populous colony in the next hive in the actual amount of surplus honey stored? Thus demonstrating that the *good queen* was in the colony which had wintered poorly, whereas the well-favored colony had only a medium or poor queen.

Dzierzon, the great German bee-keeper and scientist, says, "Queens differ much as to the degree of their fertility."

Mr. Langstroth notes an observation made while transferring bees, by counting the eggs dropt on a black cloth in 40 minutes by the queens of four different colonies. The first queen dropt but one egg, the second, 12, the third, 18, and the fourth 20 eggs, in the stated time. This observation was made in the middle of April, and on July 15th the colony of the first queen was very poor, the second was of average strength, and both the others were very strong. Now let us apply the result of this observation to practice and see how it would figure out:

Take, for instance, an apiary of 100 colonies, the average annual yield of which is, say, 80 pounds of extracted honey per colony. Let us suppose that 25 of the 100 colonies are poor, 50 average, and 25 strong, and then try to solve the problem as to how the average yield of 80 pounds per colony is obtained. The poor colonies will gather about half as much surplus honey as the 50 of average strength, or say 40 pounds each; then in order to get the average of 80 pounds per colony for the whole apiary the 25 strong colonies must gather 120 pounds of surplus honey each. Now, if in accordance with the observation and deduction of Mr. Langstroth, as already noted, the difference between the poor, average, and strong colonies, is attributable solely to the difference of queens, then we are forced to admit that the mere act of tolerating the 25 poor queens has incurred an expense of 1,000 pounds of honey when compared with the average colonies, and 3,000 pounds when compared with the strong colonies, either of the items being sufficient to pay for all the *good queens* required, and have a considerable balance to the good. You may change the figures as you desire and the result will always show that the *poor* queens are heavy debtors, with no prospect of paying, and should under no circumstances be tolerated.

Keep the best, and only the best—the *very best* are the cheapest in the end—and an economy that prohibits the employing of the best queens is certainly a false economy.

The owners of Ayrshire, Jersey, Holstein or other stock, do not stop at merely knowing that their animals are thoroughbred. Their ambition is that each individual member of their herds shall be the very best of its kind;

and should not bee-keepers study their own interests by copying the example of the stockmen in this regard? Yes, by all means.

One point more in this connection, and one which many bee-keepers scattered over the Province will do well to study and ponder carefully, and that is, the fact that the stockmen find that it pays to be a member of the Provincial Association, which is studying and advancing their interests.

Bee-keepers in the remote parts of the Province, into whose hands the Government Report may fall, will please make a note of this, and remember at the same time that the Ontario Bee-Keepers' Association is studying to advance your interests, and, like the stockmen, you will study you own interests by communicating with the secretary, Mr. Wm. Couss, of Streetsville, and secure membership in the Association which is trying to do you good.

In conclusion, I would say to those who have come expecting to hear a flowery dissertation on scientific queen-rearing; and to those who may have wished that their favorite kind or race of queens would get an advance in the address—if such has been your anticipation, I can only tender you my sympathy in your disappointment. I said at the outset that we had met for practical purposes, and I have endeavored to give you a plain, practical talk on the topic assigned to me, and I hope my address and the discussion which will follow may prove a practical benefit, not only to those gathered in convention here, but to many of our fellows who are not privileged to be with us.

Ontario, Canada.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

SICKNESS IN THE HOME.

Our readers will wonder why the break in "The Home Circle." The cause is not far to seek. One of the links in our home circle snapped for the time, and the writer was the link. Strange what a difference it makes in the home when Sickness lays her heavy hand upon one of its members. My stomach, which has always been my weak member, became for an entire week the warring member. It struck—not for higher wages, but for less work. At least, that's what the doctor says. He says it's a warning. I repeat the thought above—how shaded the home seems when Disease forces her unwelcome presence into it. The well ones try to look cheery as the best medicine for the sick one, but it is such a perfumery cheerfulness that even the dulled vision of the sick one sees that it has not in it the genuine quality. From every point of view, every home circle should make it its chief study to keep this unsavory presence—sickness—from its midst. I am sure if "The Home Circle" to-day is made a little sadder by hints and suggestions regarding health and nursing, I will be more than pardoned.

There is no doubt that we are all agreed as to the importance of every member of "The Home Circle" working with both sleeves rolled to the elbow to court the best health and vigor. How to keep well, and be at our best physically, is a most important question. Our nation and people are making gigantic strides in a business way. Our commercial activities have taken a stupendous leap, and we are rapidly distancing all the other great nations of the world. Britain is alarmed, and even phlegmatic Germany is aroused at the threatening peril. Is there not reason when our balance of trade last year exceeded Germany's entire export trade? This is all very cheering. But all this implies nerve, excitement, and if this is to keep on, as it surely is, it behooves every one of us to study how we may keep our health away to the top, that our balance in vigor and strength may even exceed our balance in trade.

HINTS ON KEEPING WELL.

I wish, now, to give some hints in regard to keeping well, which I am sure may well be observed by us all.

In the first place, we should remember the motto of the successful business man—"Outgo must always be less than income." We may well remember Macawber's words to David Copperfield: "Annual income, 20 pounds; annual expenditure, nineteen six; result, happiness. Annual income, 20

pounds; annual expenditure, 20 pounds-six; result, misery." So, too, every one of us should study the health ledger. Is the outgo of energy in excess of the income of strength and vigor? Do the scales show that there is a daily or weekly loss? Do the lapsing energies as the morning clock stroke calls to duty show that our balance in the ledger is on the wrong side? Are there little, insidious ailments, like cough, headache, indigestion, that show that we should study more intently our physical status ere we find that health is gone to return no more? I think it is a safe rule to observe, never to tolerate the presence of ache, pain, or any bodily ill. If we find that such are with us, let us rest, change our habits, try anything to reach again the full equilibrium of our physical pose.

I fear too many of us are under the strain of excessive work. We are in it. It seems valuable to the community. We dislike to drop it off, any bit of it. How much better to drop a little than to have to give it all up, especially as the giving it all up will give us also a heart full of regret. I doubt if there is any phase of gospel truth which our people need more than this. We are caught in the whirl of national push and progress, and rush on without thought of the sure consequences. Paul knew, "Let your moderation be known."

Another evil which lays its heavy hand upon our American homes is that of irregularities. I doubt if any of us fully realize the importance to health of regularity in our daily habits. How many of us always breakfast, dine and sup at the same hour every day? How large the number of those who have no settled time to betake themselves to bed or to rise as the morning hour calls to duty and service. We can well learn a lesson from the dairyman in this respect. He finds that unless he feeds his cattle at the very same time each day, a greatly lessened milk-supply informs him of his mistake. Indeed, if the cow is not milked at exactly the same time, the foam of the pail comes not so near the top. Even a change of milkers makes itself felt in the pail and pocket-book. We can hardly believe that the cow is as sensitive as "the human form, divine." If the cow is so materially disturbed by the lack of regularity, what may we conclude as to the effects of the glaring irregularities which enter so boldly into most of our American homes?

Who of us has not felt saddened as we have past thru the streets of great cities late at night, to see little children, whom Sleep should long since have claimed as her own, still thronging the walks? The very dash of our business-life makes it hard to preserve regularity in our home living. Society and business habits both offer a great premium on the habit of irregularity. Many of us have neglected our first caution, and so with Saturday night comes a threatening and overpowering weariness. This of necessity carries the sleeping hours of Sunday morning away into the day. Breakfast comes an hour or two later than on week-day mornings. Dinner instead of at twelve or one, reaches on to two or three, while supper very likely is omitted entirely. All the time the god of disease is dancing with very joy.

I know of two children that came into a home to bless and cheer it. I think neither would have been called very robust. The parents of neither were very strong. One of those children never had a doctor until maturity called her from the home circle. The other was hardly less fortunate for only once was a physician summoned, and that during the first trying summer, just at the critical time when the first year had made its span. Until well in their teens, these children were always in bed at just the hour which for all the first years was the good, early hour of seven. The meal-time in that household rarely varied ten minutes, and this not simply on week days, but also on Sunday. I wish I could say something to impress upon our American people the importance, physiologically, of the observance of absolute regularity in the home life.

A third factor in maintaining good health in the household—perhaps in importance it should rank first—is the matter of good air. This is a free gift from God, and yet how many refuse even to take it. Southern California has a well-earned reputation for its salubrity of climate. Many come here that are held down by the fell grip of consumption, and soon find full recovery of health and strength. In most cases such receive permanent cure in case they remain in this goodly climate. I believe the great reason why so many find Southern California so helpful in regaining health and vigor, comes from the fact that here they breathe good, pure air. Our climate here, even in midwinter, is like the June of Michigan and New York. Warmth and sunshine come with each day and lure even the invalid out of doors where he may take full draughts of the blessed, life-giving oxygen. Many here in Southern California live the winter thru in tents, and

thus, while they avoid all draughts, they are constantly bathed in an atmosphere almost or quite as pure as that outside.

I believe one of the greatest of health reforms would come if we could only convince our people that it is impossible to sleep in too pure an atmosphere. I would have all the windows open in the sleeping room, winter as well as summer, and the doors open into adjoining rooms also well ventilated. The sleeping rooms should be large, and it were better if only one person occupied the room. Indeed, we can not take too much pains in our sleeping rooms, that we may secure, even in the cold days of the Eastern winters, as good air as the we slept under the open skies. In my own case, I have never been overparticular to keep the draughts from myself or children, and to-day they do not disturb us. However, I would not advise those who feel disturbed if they are in the current of air, to subject themselves to draughts. The very fact of the unrest will work mischief and very likely the draught *per se* do harm.

Another thing that will tend to lessen the disquiet of such ample ventilation in the cold winter nights is a full supply of covering. Let us court the breezes and the full vigor which the pure air will give us, but let us rest under such warm coverings that we will never wake in the night with a feeling of chill.

Consumption is, perhaps, the most-to-be-dreaded disease which steals in upon us to rob us of our loved ones. We know now, of a certainty, that it is not inherited. We do know that it is contagious, tho not so readily contagious as many other microbe diseases. If we will only fling open our windows and let in the pure, blessed atmosphere, sweet and clean as God has given it to us, we shall do very much to keep this grim presence from our home circles. We shall at the same time brace up the general vigor of the body so that other diseases which may be lurking hard by shall not find ingress into our beloved homes.

The last point which I shall urge in this article toward maintaining health is that of diet. I think without any question, the most of us eat too much. Our hard work, and very likely the fact that we have gone beyond the usual meal-time, has made us ravenous, and we can hardly wait the time of meal coming. The overthirsty horse left to itself at the watering trough will often in its greed for drink take so much water that death or lasting disease results. When we are so hungry, we are apt to eat rapidly, and before the appetite is satisfied we have overtaxed our digestive powers, possibly to our lasting injury. One of the wisest things to prevent this mistake is to cultivate assiduously the habit of conversation, and the best of social times at the table. This takes the attention, causes us to eat more slowly, and thus we feel satisfied before the stomach is unduly distended or the digestive powers too greatly overtaxed. Anything that tends to slow eating at the table is worthy fullest consideration in this relation of maintaining good health.

In a coming article, I shall aim to show how a happy, sunny disposition aids to keep disease from the home circle. Thus glad social intercourse at the table, does double duty, for it not only retards the food-taking, but it also ministers to the cheer and gladness of the circle about the table. We shall continue this subject in our next article when we shall not only discuss the sunny habit, but also give some hints regarding nursing.

CITY CHILDREN.

A problem of our time and country is what to do with the city children. A friend remarks that obedience among children is a lost art. He says no children now obey. Another friend says, The great danger of our time is irreverence. I believe both magnify the evils. If these sins are on the increase, is it not the result of such herding of our children as city and town life necessitates? I hope all our readers will think over this problem. In my next article, I shall tell how a friend has attempted to solve the difficulty in part. I have ever felt to thank God that my childhood was spent in the country. I am equally glad that idleness was a stranger to my childhood days. How can we occupy the city children and preserve them from evil companionship?

"The Hum of the Bees in the Apple-Tree Bloom" is the name of the finest bee-keeper's song—words by Hon. Eugene Secor and music by Dr. C. C. Miller. This is thought by some to be the best bee-song yet written by Mr. Secor and Dr. Miller. It is, indeed, a "hummer." We can furnish a single copy of it postpaid, for 10 cents, or 3 copies for 25 cents. Or, we will mail a half-dozen copies of it for sending us one new yearly subscription to the American Bee Journal at \$1.00.

* The Afterthought. *

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

SWARMING ON TEN FRAMES.

It is rather a surprising result to find more colonies on ten frames swarming than of those on eight frames; but I do not wish to cast any discredit on the experiment. Mr. Davenport does not claim it as a *rule*, to be found good in all years and all locations. The rationale of it seems to be that *sometimes* two more frames lead to an increase of population without which swarming would not have occurred. Page 150.

MEASURING BEES' TONGUES.

Wise chap of beedom, don't you know you *can not* measure a man's tongue—not to mention the other half of animate nature, to which the bee belongs? A tongue is a thing with great capacity for rubbering round. Best understood not by what it measures, but by what it does. Thus we reflect on the words of Adrian Getaz, page 150. Indeed it *does* seem to call for some explanation, how all the other members of the bee seem to be so uniform, and tongues alone *reported* with such variation. I can very heartily second the suggestion that all measurements of a surgical character should be regarded as tentative to a certain extent—useful and desirable, but not to be regarded as final, till confirmed by live bees of the same colony taking actual sweet out of an actual cavity. Something better than the old inclined plane and wire screen ought to have in sight, to keep pace with the Twentieth Century. Too much depends upon keeping it level, and too many bees have to work at it, and work at it too long. Who'll give us a bunch of glass clover-tubes—or put two rectangular slips of glass together a twentieth of an inch apart holding honey between? The idea of the latter is that bees will quickly take the sweet out from all the edges as deep as they can reach, and leave things so as to be clearly measurable.

THREE "AFTERTHOUGHTS."

A new edible for bees—and prohibition States—"cold water soust." Page 152.

Pretty bad score for house-apiaary, 16 queens lost out of 26, and that in spite of vertical painting in strong colors. Page 153.

How about the bee-man who would fain exhibit to a wondering world 30,000 pounds of snowy sections from posies not in bloom yet? Counting unhatched chickens hardly "in it." Page 164.

A VERMONT COUNTY VS. CALIFORNIA.

And so in Vermont one county produces $\frac{1}{2}$ of all the State product, and one forty-fourth as much as California produces. How much better to fish in a little brook where there are some fish than in a big, landscape-adorned river where there are next to none! Page 155.

ANOTHER AFTERTHOUGHT TRIPLET.

Archer L. White's experiment indicates that the solar gets less than a third of the wax from old comb, in fact less than a third of what can be got by a better process. Page 159.

Two chestnuts sometimes better than one. When you trot out that aged honey-moon-honey-comb conundrum tell 'em also that the man who isn't sold for once in his life is sold for his whole life. Page 153.

"Specks the Vermonters mist it a little on the comb-building question. Presumably the fresh nectar from the fields is at least a *little* better for comb-building than it can ever be again after it is sealed once. Page 153.

THREE QUEENS NEAR EACH OTHER.

That three young queens should remain near each other some time without coming to a fight I do not consider so *very* strange. Perhaps they were cold. And I guess E. Ginner's quart of bees (or the remnant of them) did not consider themselves a colony at all—only as individuals, there because they knew not what else to do with themselves—and so paid no attention to the queens whatever. Page 156.

CLIPPING SLIGHTLY FOR NEAR-BY MATING.

I had supposed that clipping a young queen's wing *slightly*, to prevent her flying away so far to mate, was to

some extent practical. Mr. J. M. Rankin's experience of 64 failures out of 65 is rather in the nature of an extinguisher on that way of controlling mating. Page 165.

SCORING THE SCORE CARD.

The score card on page 166 affords abundance to think of and talk about. I'd Carrie Nation the "honey-wine" the first thing. "Specks there is no such thing. All wines from fruit-juices. Name "honey-wine" would be used to cover vile inventions a grade below hard cider, and on a par with the barbarous drinks of the Philippines. They call their pizen-juice wine (vino.) If we must get drunk let's get drunk on something orthodox.

There seems to be an oversight in giving the single-case display the same pointing as the general display. We read, "Variety 5." This is all right for the general display; but it is not at all desirable that a twelve-section case should contain twelve kinds of honey. Let "Variety" in that place be changed for "Uniformity," unless something more important is thought of.

I suppose "Purity" in the beeswax class means freedom from dirt. Any impurity of the adulteration sort ought to disqualify altogether. Might not a less ambiguous word than purity be found?

I doubt the propriety of putting in the style of observatory hive as a minor item toward a premium on a colony of bees. Let any style that shows the interior well suffice; and then let observatory hives have a premium all to themselves, if desirable.

"Quietness of bees" is a point so important that we dislike to discard it; yet at a fair, it is a very tough thing to judge with any sort of justice. One lot will be tolerably quiet, and another lot running wildly, from causes not much connected with the normal manners of the bees at home in the apiary.

Personally, I should prefer to vice-versa the figures in "Quality 25, Attractiveness 50;" but perhaps the brethren will like it as well just as it is.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Swarming Management.

I have two colonies of bees that are very strong at this time, but I would like to increase only to three colonies the coming season. As I know that both will swarm, and that early, what do you think of this way of handling them? Say if No. 1 swarms, hive the swarm, then remove No. 2 to a new stand and set the swarm on the old stand of No. 2. I think if this is done in the middle of the day, when a great many field-bees of No. 2 are out, they will return to the old place and enter and help the new swarm by this, and will reduce the colony of No. 2, and will thus not prevent the swarming of No. 2? PENN.

ANSWER—It may prevent the swarming of No. 2, but not certainly. It will certainly make the swarming of No. 2 later, if it does not prevent it.

Italianizing—Other Questions.

1. Would it be profitable to Italianize, where there are black bees within half a mile of my apiary?

2. Would you advise the use of full sheets of foundation?

3. Is light-brood foundation as good as the medium to use on wired frames?

4. Is the Simplicity hive as good as the dovetailed, in the production of comb honey?

5. Would you advise larger than an eight-frame hive for comb honey?

6. Would you advise the use of an observatory hive?

I have one which I made this winter, but I did not know whether it would pay me to buy the glass for it.

IOWA.

ANSWERS.—1. Yes, even if they were only an eighth of a mile away. Even if you have nothing but hybrids it will be profitable.

2. Yes.

3. Yes, if the wiring is close enough. Try it a little carefully at first if you are not sure about it.

4. You would be likely to find no difference in the amount of honey, but the Simplicity is hardly so simple as the dovetailed. If you try the two side by side you will be likely to prefer the dovetailed.

5. For some the 8-frame may be best, and for some the larger. The 8-frame requires closer attention, and even with good attention you will be likely to have some colonies starve in them every winter.

6. There is no particular profit in an observatory hive, but it is a pleasant thing to be able to see the bees at work in one.

Seems to be Paralysis.

I mail you a box containing some dead bees. I have three colonies that are dying off very fast from some cause, and I think you can tell me what is the trouble. You will see some are shiny and black. One colony is dying, and is all shades and colors. They are mated queens, bees that seem the worst. The honey they wintered on wasn't the best, but I have five or six other colonies that seem all right. Would I better destroy the diseased colonies, or will they be all right when warm weather sets in? Do you think it is *paralysis*?

The bees of the colony from which I send you specimens do something like this: They will catch or bite all around certain ones of their number, and finally the one that receives such treatment will roll off the entrance-board on the ground, kick around and die; and at evening they will crowd upon the end of the hive and expire, from 15 to 25 and sometimes more a day. It doesn't seem to make any difference whether the days are warm or cold, and they will lift the wing and try to fly, but can't do it. On mashing them there is a thick yellow substance that mashes out of the body. The ones that are well are carrying in pollen.

KANSAS.

ANSWER.—It seems to be a case of paralysis. Altho many cures have been offered, unfortunately nothing seems reliable. Fortunately it is not contagious, and it is quite possible that it will disappear of itself. The most you can do is to take good care of your bees, seeing that they are well furnished with stores, and not allowed to become weak without uniting, and then hope for the best.

Wants to Start Again With Bees.

My bees all died with the cold last winter. I have a patent hive and the frames of comb in it are all right. If I had a queen would she live and hatch in it? How many bees would she need?

ONTARIO.

ANSWER.—A queen alone would be of no value, as she would hardly live 24 hours. With bees enough to cover two combs, she should make a pretty fair start. You will find queens advertised in this journal.

Moving and Feeding Bees.

I bought an apiary, or a wreck of one, and wish to move it one mile. In that yard I find other empty hives not in use, and they are full of moths. Several colonies flew lively this week, two of which were robbed and killed, and at other hives the bees group in heaps around the entrance. Others died of starvation and I think the balance are short in stores. They are packed, and I can not examine them at the present place, nor can I get to them to feed in the hives, neither can I use entrance-feeders.

1. Will I have to build them up before I can move them?

2. Is it safe to move them in their present condition?

3. Are they likely to consume what little honey they have during the excitement caused by moving?

4. How would you like this way of feeding? I would feed them in or near the yard, by taking a large wooden

tray and laying gunny sacks in them. Over this I would pour enough feed so that they can sip all day. The next day I would do the same, but add more water, the next day still more water, and so on until it will all be water.

ILLINOIS.

ANSWERS.—1. The only trouble is that moving will excite them so as to make them consume more stores, in which case the moving would be the worse for a colony on the point of starvation; but if a colony is alive at all it will probably last long enough to be fed after moving.

2. I don't see why it is not, if the weather is at all favorable. In freezing weather a very weak colony might be so demoralized by moving as to hasten its death.

3. That has already been hinted at, but even if they do take it all into their honey-sacs it will last them for a time longer.

4. The plan will work very well if the weather is warm enough for bees to fly, and we ought to have that kind of weather now. But don't bring them down to pure water too rapidly.

Overboiling Sugar Candy for Winter Feeding.

On page 201 "Iowa" gives his experience with cakes of candy made of granulated sugar as winter feed for bees. My experience with candy as a winter feed is similar to his. Only a short time ago I examined some colonies with candy above the cluster; one colony was so nearly destitute of honey that none could be seen, and the bees had begun to die, and yet there was a large cake of candy on the frames, but the bees had not touched it. I melted the candy and gave it to the bees in liquid form. Had the weather been too cold for the bees to take it, in this form I should have poured some quite warm water all over the cake of candy. Warm water will penetrate and soften the hardest candy very readily, and so makes it available for the use of the bees.

SUBSCRIBER.

ANSWER.—This suggests that such cases may not be so rare as I had supposed. Here is something that may throw a little light on the case. In the British Bee Journal I find the following: "The sample of candy sent is quite useless as bee-food, being hard as a stone. It has been overboiled, and may be truly described as a 'hard-cake.' May not overboiling be the solution of the problem?"

Candied Honey in Brood-Combs—Spraying While in Bloom.

1. I have about 500 brood-frames full of combs and honey, that are in good shape, smooth and square. There is 1,000 or 1,200 pounds of honey in them. The trouble is they are three and four years old, and the honey candied. Will they do to use this season? If not, what is the best way to dispose of them? They are all built on comb foundation.

2. Would you advise keeping bees in an orchard? It is about two-thirds grown. They do not get the sun much until about nine o'clock in the morning. They have plenty the rest of the time. I could give them the morning sun, but it would bring them within about five rods of the road. Would I be likely to have trouble?

3. I am in an apple section, and some orchardists are bound to spray when the trees are in full bloom. They did so last year within ten rods of my apiary. I talkt with them, and they said they could spray when they liked, and that I could keep my bees at home. I brought the question of spraying before the farmers' institute, and proved to them that they injured their fruit, and that they laid themselves liable; but they have been told that before. I am a farmer myself, but at present I am in the bee-business.

NEW YORK.

ANSWERS. 1. Sprinkle them with water and give them to the bees. If necessary, repeat the sprinkling.

2. It is not likely the shade will do any harm.

3. Send a dollar to the editor of this paper or to the general manager of the National Bee-Keepers' Association, so as to become a member of the Association, and the manager will furnish you literature with which you can instruct your neighbor, and give you any assistance needed. Of course you may get along without joining the Association, but you'll get along better with it, and be helping others as well as yourself.

DESKS FOR GENTLEMEN AND LADIES!

Combined Desk and Book-Case

Size, 66-in. high, 36 in. wide,
19 in. deep.
Price, \$13.75.

THESE DESKS are made of quarter-sawed oak, first-class finish, well put together, and will please every purchaser. They are an ornament to any home, as well as being a useful necessity. Would make a FINE GIFT for father, mother or sister.

The Combination Desk and Book-Case

is just the thing for a farmer or business man of any kind, to keep his private papers in, and for his books, etc. The drawers have locks, and there are a number of pigeon-holes inside each of the desks shown herewith.

The low prices quoted are f.o.b. Chicago. Send for free catalog. Address,

The Royal Star Combination
Game-Board Co.,

773 to 779 Carroll Ave., CHICAGO, ILL.

Wintered Without Loss.

My bees have wintered on the summer stands without any loss, but I am feeding now. I have 12 colonies in 15-frame hives, but I take out three frames from each side of the hives when I pack the bees for winter. Hall Co., Neb., March 23. FRED RUBY.

June-Berry—Blacks Ahead.

Kindly inform me what this flower is I send you. It grows on our hills on small trees, and looks like dogwood trees. It is in bloom with peach-blossom and elm. I do not know whether bees work on it or not, as I never noticed the bloom before to-day, when I was up in the mountains. I think it is linswood. It is very fragrant.

I have not been in the bee-business long. I have about 50 colonies, and know but little about honey-producing flowers and plants.

The weather has been so open and mild here that my bees have eaten up nearly all their winter stores, and I find my Italians have consumed a great deal more than the blacks. I had only 11 colonies of Italians, from queens I introduced last year. They went into winter (as I thought) with abundance of honey, but last month when I examined them I found two starved to death, and almost every Italian colony very short of honey, and I fear I am too late in feeding to do them any good.

With my short experience I find the blacks away ahead of the Italians. I had one new swarm of blacks that stored 250 pounds of comb honey, besides enough to winter on.

R. N. CRAFTON.

Indian Territory, March 27.

[The botanist of the American Bee Journal reports as follows on the flower specimen sent by Mr. Crafton:—EDITOR.]

The specimen you send for identification is the June-berry. *Ancistræberis canadensis*—and belongs to the pear family. The June-berry is a small tree or shrub, and sends out its

white, showy blossoms before the leaves appear, thus making itself very conspicuous even from quite a distance. The blossoms appear in April or May, depending upon the season and latitude, and the purplish, edible berries, in June. It is an indifferent honey-producing flower.—C. L. WATSON.

Wintered on the Summer Stands.

Last year was a poor year for honey in this locality, but my 41 colonies came thru the winter all right, on the summer stands.

We have an abundance of white clover, but there are very few bees kept here. I can not do without the American Bee Journal, as I have learned from it all that I know about bees. ALONZO GRANT, Clark Co., Wash., March 18.

Report from a Young Bee-Keeper.

Our bees have wintered well and are in good condition for spring work. My father used to think that he had the best of bees, but he has found that they can be improved upon. He bought three queens from a prominent queen-breeder, and all proved to be very good ones, tho one of them was especially so, and he selected that one from which to rear queens. She reared over 70 queens, and only one of them was poor.

We secured a very poor honey-crop last season, but we are watching and hoping for a good crop this season.

EMMA BANKER (age 14).

Brown Co., Minn., March 24.

Better Prices for Honey.

Will some one please tell me, as well as the rest of the readers of the Bee Journal, how we can bring about a speedy combination of the bee-keepers so as to get a better price for our honey here in California, where honey is produced by the car-load—yes, even by the train-load? The population is not so great as in the East, where from 2 to 100 colonies of bees are kept, and where honey enough to supply the demand can not be secured. We are at the mercy of the jobbers, who are not disposed to "live and let live," but want all.

If joining the National Bee-Keepers' Association will help to rectify matters, I would like to know it; and, if so, I will do all in my power to promote the good of the National or any other association that will help us out.

Would it not be well for the National Association to have a set of by-laws printed and sent to all bee-keepers, and advise combination? We see, and hear, of combinations formed every day with immense capital, and they succeed, so why couldn't we? If every bee-keeper would contribute \$2.50 it is hard to estimate what the amount of capital would

QUEENS!

Improved Golden and Leather-colored Italians as well as **H. G. QUIRIN** rears.
We have one of Root's best long-tongued Red-Clover Breeders from their \$200 queen, and a Golden Breeder from Doolittle, who says if there is a **BREEDER** of golden bees in the U.S. worth \$100, this one is worth that sum. The above breeders have been added to our already improved strain of queens for the coming season. J. L. Gandy, of Humboldt, Neb., wrote us on Aug. 5th, 1930, saying that the colony having one of our queens had already stored over 400 pounds of honey (mostly comb); he states that he is certain that all his bees work on Red Clover, as they were the only kind in his locality and apiary.

A. I. Root's folks say that our queens are extra fine, while the editor of the American Bee Journal tells us that he has good reports from our queens from time to time. We have files upon files of unsolicited testimonials.

After considering the above evidence, need you wonder why our orders have increased each year? Give us a trial order and be pleased. We have years of experience in mailing and rearing queens. Safe delivery will be guaranteed, and instructions for introducing sent with lot of queens.

QUEENS NOW READY TO MAIL.

Warranted stock, \$1.00 each; six for \$5.00

be, but I suppose at least \$1,000,000. That would make a neat little "combine."

Our prospects are very fair for a partial crop of honey this year. C. E. STEVENS.
San Diego Co., Calif., March 25.

Drones of Ye Olden Time.

The practice of cutting out drone-comb is no new thing. Plato, who was born some 400 years before the Christian Era, in his "Republic," represents Socrates as saying:

"Now the presence of these two classes of idle and extravagant men which we may compare to drones—like phlegm and bile in the body—breed in every commonwealth disturbance. Therefore, a skillful physician and legislator, just like a cunning bee-keeper, must take measures in advance, if possible, to prevent their presence, but should they make their appearance, he must have them cut out, as quickly as possible, along with the combs themselves."

This passage is interesting because it serves to show that the Greek bee-keepers of Plato's day must have had some sort of a hive which enabled them to handle the combs. It also indicates that they knew a thing or two about keeping bees. Mr. Duda, in his articles impressing the importance of cutting out drone-comb, has the satisfaction of knowing that he is in line with ancient example and precept.

The winter has been favorable here for bees. All colonies, so far as heard from, have come thru in good shape. I have wintered my bees on the summer stands for four years now, and have yet to lose my first colony. I fill the supers with planer-shavings, and protect on the north and west with CRACK PARKS.

Lancaster Co., Neb., March 25.

Better Prospects Than for Years.

Bees in this valley were rather backward at the beginning of the year, but now they are breeding up very fast, and the prospects for a honey crop are better than they have been for years.

WM. ROSS.

San Bernardino Co., Calif., March 19.

Bees Wintered Nicely.

My bees wintered well, and I think all bees did in Ashley Valley. I lost only 6 colonies out of 90; there are 6 that are short of winter stores, and I am feeding them. Bees are gathering pollen and the prospects for a good season are fine. There is lots of snow on the mountains.

BENJAMIN A. VAN DINE.

Utah Co., Utah, March 23.

Flowers and Fruit-Trees Blooming in Florida.

In Florida it is not the "Hum of the Bees in the Apple-Tree Bloom," but the hum of the bees in the yellow jasmine bloom. It is a very pretty vine, and I have seen the tops of young pines bending with the weight of its golden bloom. Lately I saw a beautiful vine clinging to the cornice of a two-story house, and winding around its cupola, shedding its fragrance on the southern air.

The titi is now in bloom, and its long, white racemes of tiny flowers are also very fragrant, and yield a nice white honey. Peach and plum-trees are also beginning to bloom—the plum-trees are very white, and the peach-trees are a deep pink. When the weather is favorable they are alive with busy workers. Many pear-trees in this vicinity have died of blight; they are of the Le Conte variety. The Reifers are not injured by it. The clusters of bloom on good pear-trees resemble those on the hydrangea. I have counted 45 blossoms in one cluster. Bees gathered much pollen from pines and cedars.

The past winter has been cool, yet there has been no severe freezing. The tender growth of orange-trees was nipped by frost on March 6th, but now the little white buds show pretty much above the shiny green leaves.

I saw a bee-keeper to-day who said that his bees were not doing much, as there had been too many cold winds. He had swarms last year on Feb. 20th, but he thinks it will be a

long time before he has any this season. His apianry is small, but apparently well kept, the bees being in movable-frame hives.

MRS. L. HARRISON.
Washington Co., Fla., March 23.

Good Report from Colorado.

Seven years ago I started in the bee-business with 2 colonies, which I bought for \$10. Last spring I had 50 colonies, and was offered \$4 per colony for them, but I refused it. My honey crop last year was 2,400 pounds of extracted honey and 2,200 pounds of comb. I sold the extracted honey at 7½ cents per pound, or \$180, and the comb honey for 11½ cents per pound, or \$247.50, making a total of \$427.50.

My increase last season was 30 colonies, but I lost 2 of these during the winter, so have only 78 now. The lowest average of honey secured, spring count, has been 40 pounds per colony, and the highest 90 pounds per colony, the latter being the average stored last season.

A. WADDINGTON.
Otero Co., Colo., March 27.

Report from Minnesota.

Our bees have wintered well, with a loss of only one colony out of 124. Last year we got no honey and had to feed our bees, but we hope for better things the coming season.

My father is going to give me a colony this year and I hope they will store plenty of honey so that I will not have to feed them. We use the Langstroth hives.

We wintered some of our bees outdoors packed in wheat chaff in boxes two inches larger on the sides than the hives, and 4 inches higher, and raised the backs of the hives a little so that the moisture can run out. We have 20 colonies in the cellar which seem to be all right, but when we take them out they may be all wrong.

FRED BANKER (age 12).
Brown Co., Minn., March 24.

Poor Prospects for the Coming Season.

I put 11 colonies into the cellar, and I think there are a great many of the bees dead.

I am very much interested in the American Bee Journal, but I think it is a waste of all we have to comfort us this summer in the bee line. If the spring is late there won't be a colony left in the country. F. DURANT.
Winneago Co., Wis., March 25.

Bees Wintered in Good Condition.

My 38 colonies of bees seem to be in good condition, and if we have warm weather for a week or two we can take them out of the cellar.

We had a good horse killed by lightning on March 26d, but notwithstanding our bad luck we feel that we must have the American Bee Journal in order to carry on bee-keeping successfully. WM. HARTWIG.
St. Croix Co., Wis., March 25.

Bees Short of Winter Stores.

The roads here are in very bad condition, and have been so for six weeks; the mud is a foot deep, and there is snow on top of that.

In February I lookt at some of my bees, and I am afraid that many will be short of stores. Maple is in full bloom, but no bees are working.

There has been no comb honey in our market for a month. I keep the extracted on hand. Four brood had cut my number down to 40 colonies. JOHN C. STEWART.
Nodaway Co., Mo., March 28.

CONVENTION NOTICE.

Illinois.—The spring meeting of the eastern division of the Northern Illinois Bee-Keepers' Association will be held at the residence of B. Kennedy, 7 miles southeast of Rockford, Ill., on Rural Route No. 5, and 3 miles northeast of New Milford, Ill., Tuesday, May 21, 1901. All interested in bees are cordially invited to attend.

B. KENNEDY, Sec.

The Farm and the Thresher.—The man who owns and operates a threshing outfit is not the only one who should study and look into the merits of threshing machines. If there is any one man above another who should be interested in the capabilities and the quality of work a threshing machine will do, that man is the farmer. If a machine is only limited in capacity and is pushed beyond its limit the grain will be "hogged," or poorly threshed and cleaned, and the farmer is the loser. If the machine be flimsily constructed, or if the engine is of too light capacity, it breaks and wears and wears, and with a big gang of threshers on his hands the farmer is again the loser. Certainly, then, when you have a job of threshing to do the safe plan is to select or employ a machine of such well-known make and ability as to avoid all these vexatious delays and losses. As a type of this best class of threshers we illustrate here with the new Rumely threshing machine which is manu-

factured by the M. Rumely Co., of LaPorte, Ind. These threshers have a most valuable reputation for threshing and cleaning ability, large capacity, durability, and earning ability. They are equipped and provided with every improvement and time and labor saving device known to threshing art, i.e., self-feeders, hand-cutters, grain-weighers, grain-grabbers, high elevators, elevators with cross-conveyors, etc. The Rumely engines which are kind of burning with attachments are made of both straw, etc., are phenomenal for their strength and durability, and further for the fact that they always develop greater than their accredited power. They are remarkably easy and quick-steers, and are economical of fuel. Their traction power is simply enormous, and they take the entire outfit anywhere over any kind of road. The operators can be equipped with Uncle Tom's Wind-Stacker, or the Salfley Attach Stacker, or the Independent Swinging Stacker, as desired by the buyer. All machines of every kind and all attachments are made of the very best material and in the most workmanlike manner. If interested in threshing machinery in any way it will pay you to send immediately a card to W. M. Rumely Co., LaPorte, Ind., to-day, and they will take pleasure in mailing you one free. But please don't forget to say you saw their advertisement in the American Bee Journal.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Apr. 8.—Choice grades of white comb honey continue to sell at 10c per pound, and there is no surplus in sight. Other grades of comb sell fairly well at the following prices: No. 1 grades of white, 14½ to 15c; off grades, 13c; light amber, 12c; dark amber, 10½ to 11c; buckwheat and other dark combs, 7½ to 10c; candied and mixt colors, 7½ to 9c. Extracted is dull, and prices very weak, with the exception of some fancy Linden and clover grades quotable at 70 to 80c; ambers, 65 to 75c; dark and buckwheat, 50 to 60c. Beeswax, 24c. R. A. BERNETT & Co.

NEW YORK, March 19.—Our market is virtually bare of comb honey, and there is a fair demand for all grades. Fancy white is still selling readily at from 15 to 16c. No. 1 white at from 13 to 14c; amber at from 12 to 13c; buckwheat, 10 to 12c, according to quality and style of package. As to extracted, the market is quiet and inactive, and a certain amount will have to be carried over again. Prices are declining somewhat, and if the honey is not sold in large lots, concessions will have to be made. We quote: California white, 7 to 7½c; light amber, 6½ to 7c; other grades and Southern, 6 to 6½c per gallon. Beeswax very firm at 28 to 29c; and for exceptionally fine yellow, 27c.

HILDBRETH & SGOELKEN.

BUFFALO, Apr. 4.—Fancy comb, 14 to 15c; dark, etc., 8 to 12c, as to grade. Demand moderate. Fancy beeswax, 27 to 28c. BATTERSON & Co.

OSAMA, Mar. 30.—Demand fair; stocks light. Fancy white comb, 15 to 16c. Extracted moving slowly at 7 to 8c for white. We do not see any particular change for the balance of the season, as present supply will just about be sufficient to supply the trade until new crop gets into market. H. W. WATSON.

DETROIT, Apr. 11.—Fancy white comb, 14 to 15c; No. 1, 13 to 14c; dark and amber, 10 to 12c. Extracted, white, 6½ to 7c; amber and dark, 5 to 6c. Beeswax, 27 to 28c.

Sales slow and stocks light, maple syrup taking attention. M. H. HUNT & SON.

CINCINNATI, Apr. 8.—The demand for comb honey is nearly over. The stock of it also well cleaned up. Fancy white brings yet 10c. Extracted is in fair demand; dark sells for 5½c; better grades bring 6 to 7½c; fancy white clover from 8 to 9c.

KANSAS CITY, Mar. 23.—Receipts light; demand normal at steady prices. Fancy white comb, 15 to 16c; no amber on market. Extracted, 8 to 9c. Beeswax scarce, steady demand, 28 to 30c. W. R. CROMWELL PRODUCE CO., Successors to C. C. GUMMERS & Co.

ALBANY, N. Y., Apr. 6.—Honey market quiet. Light supply and light demand now. The stock is well cleaned out, so will be no old honey to carry over this season. H. R. WRIGHT.

Boston, April 4.—Fancy No. 1 white in cartons, 17c; A No. 1, 16c; No. 1, 15 to 16c, with a fairly good demand. Absolutely no call for dark honey this year. Extracted, white, 8 to 8½c; light amber, 7½ to 8c. Beeswax, 27c. BLAKE, SCOTT & LEE.

SAN FRANCISCO, Feb. 6.—White comb 13 to 14 cents; amber, 11½ to 12½c; dark, 8 to 9c. Extracted, white, 7½ to 8c; light amber, 6½ to 7½c; amber, 5½ to 6c. Beeswax 24 to 25c.

Considering the light output of honey last spring from California apiaries, present offerings are of tolerably liberal volume and are mostly of good quality. The market is slow at the quotations. It is reported on good authority that adulterated and imitation honey is being dealt out in considerable quantity, which accounts in a great measure for the very limited business doing in the pure article.

1901—Bee-Keepers' Supplies!

CHAS. DADANT & SON, Hamilton, Hancock Co., Ill.

\$15.00 and \$25.00 Queens

Having a Measured Tongue Reach.

The call for queens of our celebrated \$200 imported mother
has been so great that we have decided, in addition to the \$2.00,
\$4.00, and \$6.00 grades of this stock, to offer some \$10.00, \$15.00,
and even \$25.00 of this same blood. But these prices are for tested
queens, the **tongues of whose bees have been measured.**

The \$10.00 queen is guaranteed to produce bees with a tongue-
measurement of 19-100,

The \$15.00 queen, 20-100,

The \$25.00 queen, 21-100.

These last are very rare and with one exception this (21-100)
is the longest tongue reach yet secured. We reserve the right,
when we do not have the stock with the tongue reach called for,
either to return the money or to send the next lower, remitting
the balance. It would be well for our friends to put in their
orders at once, and as soon as we get the grades we will send notice.
When the money is sent, the queens will be forwarded. These
will be put up in the very best manner possible; and while we
guarantee safe arrival in good order to any point in the United
States, on any railway line, we will not guarantee safe intro-
duction. Such valuable queens should be released on hatching
brood.

N. B.—It seems as if it ought not to be necessary to say that
no one but a queen-breeder or a large honey-producer should order
these high-priced queens; but it is a fact according to our expe-
rience that beginners with only a few colonies will order our high-
est priced imported queens. Such bee-keepers have no more use
for such queens than a pig has for a wheel-barrow.

THE AMERICAN BEE JOURNAL

PUBLISHED WEEKLY BY

GEORGE W. YORK & CO.

144 & 146 Erie St., Chicago, Ill.

*Entered at the Post-Office at Chicago as Second-Class Mail-Matter.

IMPORTANT NOTICES:

The Subscription Price of this Journal is \$1.00 a year, in the United States, Canada, and Mexico; all other countries in the Postal Union, \$0.6 a year extra for postage. Sample copy free.

The Wrapper-Label Date of this paper indicates the end of the month to which your subscription is paid. For instance, "Dec 01" on your label shows that it is paid to the end of December, 1901.

Subscription Receipts—We do not send a receipt for money sent us to pay subscription, but change the date on your wrapper-label, which shows you that the money has been received and duly credited.

Advertising Rates will be given upon application.

Reformed Spelling—The American Bee Journal adopts the Orthography of the following Rule, recommended by the joint action of the American Philological Association and the Philological Society of England:—Change "ed" or "ed" final to "t" when so pronounced, except when the "e" affects a preceding sound. Also some other changes are used.

National Bee-Keepers' Association

OBJECTS:

To promote and protect the interests of its members.

To prevent the adulteration of honey.

To prosecute dishonest honey-dealers.

Rocky Mountain Bee-Plant Seed!

(*Cleome integrifolia*.)

...FREE AS A PREMIUM...

The A. B. C. of Bee-Culture says of it: "This is a beautiful plant for the flower-garden, to say nothing of the honey it produces. It grows from two to three feet in height and bears large, clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado where it is said to furnish large quantities of honey."

We have a few pounds of this *Cleome* seed, and offer to mail a ¼-pound package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00; or ½ pound by mail for 40 cents.

GEORGE W. YORK & CO.,

144 & 146 Erie St., CHICAGO, ILL.

The Emerson Binder.

This Emerson stiff-board Binder with cloth back for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

Weekly Budget.

T. F. BINGHAM, of Clare Co., Mich., wrote us April 15th that the bees in his region had wintered fairly well, his own having been in the cellar just five months.

DR. C. C. MILLER gave us a short call on Saturday, April 14th. He is looking and feeling much better than for some time past. He said, "I feel 15 years younger than I did three months ago." The good Doctor's many friends will join in the hope that he may continue to improve, and be spared many years to help make easier the paths of questioning bee-keepers, and if need be say, "I don't know."

DR. A. B. MASON, writing us April 12th, had this to say about himself and his bees:

FRIEND YORK:—It is four weeks this morning since I had a fall and broke two of my ribs just below the left shoulder-blade. I also bruised my hip, and am still wearing "corsets." They do not allow me to lift as much as a pail of water yet, but I tell you I have a "bully" time doing nothing. I will be ready for business again in a few days.

Our bees are still in the cellar, and in splendid condition. It has been too cold to put them out, but early this morning, with the mercury at 32 degrees, it looked as if they might be put to-day, but now at 7 o'clock a m. it is clouding up, and prospects are for a cold day.

Yours very truly,

A. B. MASON.

We regret very much to learn of the Doctor's fall, but are not surprised that it should have resulted in broken bones, as he is "no small affair." When a "boy" of his size begins to drop, something has to give way when he strikes bottom. But all will hope for his speedy and complete recovery.

FIXED FOR CRUELTY TO A BOY is the heading of an item dated at Washington, April 13th, and found in the Chicago Record-Herald, which reads as follows:

Prof. Frank Benton, of the Agricultural Department, was fined \$100 by Police Judge Scott yesterday for his inhuman treatment of Frederick Hahne, an 8-year-old.

For some time Prof. Benton, who is in charge of the apiaary at the Department of Agriculture, has been annoyed by boys throwing sticks and stones at the bee-hives. On last Friday he made a raid on the boys and caught young Hahne. Taking him by one arm and one leg, the Professor carried and dragged the struggling, screaming child to the hives.

"I'll give you enough bees," said the Professor, as he held the boy in front of one of the hives. The angry bees settled on the boy, stinging him severely about the face and on the legs. As soon as he could get away the boy ran home, where he was treated by Dr. Nicholson, under whose care he still remains. John Hahne, the boy's father, procured a warrant for the arrest of Prof. Benton, charging him with assault.

The boy still shows the effects of the stings. His face is badly swollen. His father is very indignant at the light punishment inflicted by Judge Scott upon Prof. Benton. When Secretary Wilson was asked this afternoon what action he would take in the case of Prof. Benton, he said the matter had not been brought to his attention.

While we would not for a moment approve of Mr. Benton's severe treatment of the naughty small boy, still we must admit that it

is very exasperating to a bee-keeper to have his colonies pelted with stones and various other missiles. We lost a good colony of bees the past winter by its hive having been upset by mischievous boys after we had it nicely prepared for winter. The combs, heavy with honey, were all broken from the top-bars, and likely drowned the bees. At any rate it was the only colony we lost in wintering, and we can not attribute it to anything else than the upsetting, as the other colonies came thru in good condition.

But wouldn't it have been better if Mr. Benton had carried his boy into the house, set before him some nice honey and biscuit, and then explained to him in a kindly manner the probable result of his annoying the bees? It would have been cheaper for Mr. Benton, and he perhaps might have made a staunch friend out of a careless boy instead of running the risk of having the boy stung to death for causing a little annoyance.

WHAT NEXT IN THE TEMPERANCE REFORM?

—The Board of Managers of the National Temperance Society and Publication House, believing that the times call for an active and aggressive campaign of the Christian and Temperance forces against the liquor traffic, at a meeting held on Thursday, Feb. 21, 1901, instructed the general secretary to send a circular letter containing the following series of questions to a number of representative temperance men and women, with the request for replies.

The Board believes that from the replies received it will be possible to mature plans for an aggressive campaign of the united moral and Christian forces, that will make the new century memorable in the entire overthrow of the liquor traffic.

The replies will be collated and classified, and copies of the results sent to all papers printing this circular.

QUESTIONS.

1. Now that the "Canteen" citadel has been taken, what in your judgment should be the next point of attack?
2. Is a union of the temperance forces of the United States at this time desirable and practicable?
3. If so, on what basis and along what lines in your opinion could such a union be effected?
4. Would you advise holding in the near future a conference (not a convention) of representative temperance men and women as a means to that end?
5. If so, what place in your judgment would be the best, and what time the most fitting?

Those of our readers who wish to answer these questions may send their replies to James R. Dunn, Nos. 3 and 5 West 18th St., New York, N. Y.

THE SPORTS THAT MAKE THE MAN.—Sir Thomas Lipton, K. C. V. O., has written especially for the Saturday Evening Post, of May 11th, an article on this subject. He places yachting high on the list, and gives some interesting anecdotes of his own career as an amateur yachtsman. Sir Thomas is hopeful, if not confident, of "lifting" the America's Cup next autumn. He says, however, that if it were a certainty he would not cross the water; for there is no sporting interest in "sure things." This article will appear exclusively in the Saturday Evening Post, of Philadelphia, Pa. It is one of the very best weekly periodicals published to-day.

ESTABLISHED IN 1861 AMERICAN THE OLDEST BEE-PAPER IN AMERICA BEE JOURNAL

41st YEAR.

CHICAGO, ILL., APRIL 25, 1901.

No. 17.

* Editorial. *

"The Man Who Reads is the man who succeeds," is the first sentence of an editorial paragraph in the Bee-Keepers' Review. To illustrate it, Mr. W. L. Coggeshall, of New York State, is referred to. He employs quite a number of young men every season in his bee-keeping work with nearly 1,500 colonies, and he says that "the young man who did not read never amounted to much in his employ." It was a true statement, and will apply in practically every calling in life.

The man who would succeed certainly must read. He must inform himself concerning every detail of his business. He must find out the principles by which others have won success, and then adapt them to his own use.

No man liveth unto himself, 'tis said. And that is also a hard fact. We are all dependent one upon another. Each needs the other's help and encouragement, in order to do the best work. And by reading we gain not only helpful information, but a necessary enthusiasm. We thus learn how others have done successfully, and we feel that we can do as well if we make the effort.

Honey by the Pailful.—Mr. Thomas Slack, of Canada, tells in *Gleanings in Bee-Culture*, how he disposes of his crop of honey by the use of tin pails, selling direct to families. His price is \$1.00 for eight pounds. He thinks that when a family buys a pailful of honey at a time they will not use it so sparingly as when getting only a single section or a small glass jar of it. That sounds reasonable. And he says he can sell more honey at eight pounds for \$1.00 than at 10 cents a pound. No one would want to try to push the 10-cent price if the other is a success. He allows 10 cents for a returned pail.

Mr. Slack covers with his market wagon 21 miles in three directions each week in the summer. Liquid honey sells as ten to one for him as compared with candied.

"Keep More Bees" is the advice some of the leaders are giving "without charge" to those who have not made very much success at bee-keeping. The idea is that most bee-keepers have not been in the business in a sufficiently extensive way to make it pay. This may be true in many instances; in others, if the locality is not suitable for successful bee-keeping, it would simply be folly to "keep more bees."

As a sample of what at least one bee-keeper

is expecting to do in the expansion business the coming season, we may say that he has already contracted to furnish 12,000 pounds of comb honey at 16 cents per pound. He is in the sweet clover district not a hundred miles from Chicago. We are not at liberty to mention his name, as we are not certain that he cares to have it published. However, what we have given will do no harm. He is buying bees "to beat the band," and expects to have about 250 colonies, and all in one yard. He will have an expert bee-keeper take full charge of the bees, while he attends to other business that requires his attention.

Last year, we believe, this same bee-keeper averaged 100 pounds of comb honey to the colony, and had over 50 colonies in the yard. We will be able to report next fall how it has paid him to "keep more bees" this year.

There is quite a good demand for bees this spring, at least in this locality, and if any of our readers have them for sale at right prices, they should do well by offering them thru the advertising columns of the *American Bee Journal*.

Spring Care of Bees.—Editor Hill gives this paragraph in the April *American Bee-Keeper*, which should be read, and its suggestions followed, by every one who desires to make bee-keeping a success:

At no time of the year does skillful treatment and care of the bees yield so great a reward as that bestowed during the spring months. Avoid handling unnecessarily at all times, and under no circumstances do so while the weather is cold. See that all colonies are provided with queens and with ample stores. Brood-rearing draws heavily upon the honey which they may have. Protect the hives in every possible way against the loss of heat. Upon the number of eggs laid by the queen up to the 37th day preceding the opening of the bloom from which the nectar is to be gathered, depends the bee-keeper's success. All laid thereafter are at a loss to the honey-producer. Give the queen the benefit of every advantage you are able to bestow. In order that she may meet the honey-dew with an ample force of workers.

Testing Barrels for Honey.—In all probability wooden barrels will be used for holding honey, for many years to come. Altho the tin can is fast becoming the more generally adopted package for shipping extracted honey, still there are localities and purposes which demand the barrel. So we say, every man to his liking or preference. Pres. N. E. France, of the Wisconsin State Bee-Keepers' Association, is perhaps one of the most extensive user of barrels for holding honey. He is a very candid man, and can not be induced to use a can for honey. But he knows how to test a barrel before putting honey into it. At the convention in February

he gave his method as follows, the Bee-Keepers' Review furnishing the paragraph:

"Barrels may be tested as to whether they will leak by blowing or forcing air into a hole in the head; but there is a peculiar knack in doing this. One breath alone will not test the matter. Put the lips or mouth close upon the aperture, and blow in all the air that can be expelled from the lungs; draw in another breath thru the nostrils, still holding with the lips the pressure obtained by the first breath; blow in another breath; hold this and draw in another. Perhaps a part of the third breath may be forced into the barrel, but that is about all. Hold the pressure. If there is a leak, the pressure will soon run down, and the ear may detect the sound of the escaping air. If there is no leak, the pressure will remain; and upon removing the mouth the air will come out of the opening with quite a decided explosion."

Done at the Right Time.—G. M. Doolittle says this in the *Progressive Bee-Keeper*, about doing things in the apiary at the right time:

"Upon their being done at the right time depends the success of many of the operations of the apiary. From what we often see, it is evident that all bee-keepers do not realize this. The wise man said in the Scriptures, when he wrote under inspiration, 'To everything there is a season, and a time to every purpose under the heaven,' and tho he was a preacher instead of an apiculturist, he could have done little better had he been the latter; for unless the manipulations and operations in the apiary are done at the right time, and in the proper season, our purposes, no matter how good, will fail of the desired success."

Weak Colonies in the Spring.—In the April Bee-Keepers' Review Editor Hutchison has this to say about the treatment of weak colonies in the spring:

Weak colonies are something that, it is almost universally agreed, are not worth fussing with in the spring. Uniting them does not seem to help matters much. Several times have I united two or three weak colonies into one in early spring, taking out the extra queens and selling them, only to find, a few days later, the newly formed colony no more populous than was one of the colonies that were used in its make-up. Then I would again unite two or three of these made-up-and-run-down-again colonies, only to see them again reduced in numbers. I believe that once, when warm weather came, and the bees finally began to build up, I had the remains of a dozen colonies all in one hive. There is something about this matter that I don't exactly understand. Here are three weak colonies. We unite two of them. A week later it is difficult to say which is the colony that was made up from the two, and which is the one left to itself. See that your weak colonies have sufficient food, tuck them up snug and warm, and then let them alone—and that is good advice to follow with strong colonies.

The Necessary Bee-Supplies. Have you them on hand, all ready for use when wanted? It is very aggravating to be compelled to wait for the arrival of supplies when the bees are suffering on account of their delay.

GHENNADJ KANDRATIEFF.

As the present ambitious strides of Russia towards aggrandizement are drawing the attention of the civilized world, it may not be amiss to show what is being done by some of its inhabitants in more peaceable lines. War is surely not a sign of progress, but the quiet pursuit of practical apiculture is one of the growing sciences, which are followed only by civilized men. So on the first page we give the photograph of a leading Russian apiarist.

Mr. Ghennadj Kandratieff was born February 5, 1834, on his hereditary estate of Sazikino, ten versts (a verst being 3,500 feet) from the city of Yrimeschma, in the province of Kostroma. His father, a retired colonel, was then living at Sazikino and was the "nobility marshall" of the province. Being an old soldier of the time of Souvoroff, he desired his son to embrace the same career, and sent him, at the age of only seven, to the military Corps Alexander, for children. From this, in 1854, little Kandratieff was sent to the Corps Paul, of the Cadets. In 1853 he was transferred to the regiment Model for the study of cavalry service, and lastly, in 1854, he obtained the epaulets of an officer in the regiment of Cuirassiers of the Grand Duchess Helen Pavlovna.

During the Crimean campaign, Russia was short of officers, and a call was made for volunteers; among these Mr. Kandratieff was placed as a cavalry officer at Sebastopol; at the end of this campaign, after the close of the war, when it became possible for him to quit the military service, he obtained his discharge and gave himself up to his favorite occupation—music.

His talent, his exceptional ability, and his passion for music, had shown during his earliest infancy, and during his military education, while still a boy, he already led the choirs of the cadets in the church.

At length, after numerous difficulties, he succeeded in leaving Russia to go to Italy, the country of music and fine arts.

There, during the first four years of his sojourn, he studied with zeal the Italian language, the Italian song, declamation, everything, in fact, which has any relation with scenic art. In 1860 he made his first appearance on the Italian stage, as first bass in the opera of Rossini—Semiramis. This "debut" was very brilliant, and after that he was for four years engaged in twelve of the leading Italian theaters, upon whose stages he filled with great success several roles of his profuse repertoire.

His artistic career was triumphal, and on the first of September, 1864, he was called back to Russia, for an engagement with the Imperial theater of St. Petersburg. He remained there as a singer until 1872, after which time he was appointed general manager of the Imperial Opera, which he managed until September 1, 1900. While he was occupying this position, which required great knowledge, strength of character, coolness and presence of mind, these occupations disturbed his nervous system to such an extent that the doctors advised him to seek for a summer occupation that would compel him to remain all day in the air and sunshine. He had become a member of the Free Economic Imperial Society, and had made the acquaintance of the celebrated professor of chemistry of the University of St. Petersburg, the great apiarist, A. M. Boutleroff. The latter induced him to go into apiculture, and Kandratieff took such a taste for this pursuit that now a life without bees seems to him a life without aim and without interest.

In 1878, Kandratieff and Prof. Boutleroff, who had thus become quite intimate, being both members of the Apiarian Commission of the above-named Imperial Society, were put in possession of 200 dimes of land, on the shores of the Black Sea, not far from Souhoum-Cale, for the rearing and cultivation of bees after rational methods. They then began regular visits to this distant apiary. Mr. Kandratieff even now remembers with pleasure those trips which they usually undertook during the fine season, in the months of April and May, the best time of the year in Caucasus. They would go by rail to Sebastopol (still in ruins since the Crimean War), from there in a carriage to Salta, and thence on a steamer which stopt at all the ports

on its way to Batum, whence they took another steamer for Souhoum-Cale. These voyages left with them interesting reminiscences and happy impressions.

Unhappily these pleasurable excursions soon ended. Prof. Boutleroff died suddenly, and in the same year Kandratieff lost his only son, who was feeble in health, and for whom he had hoped to create at Souhoum an earthly paradise, for this section of country is celebrated for its climate. After the boy's death the sale of the apiary was decided upon.

In 1880, Mr. A. Boutleroff founded the first Russian bee-journal. After his death it was managed for some time by the celebrated Russian apiarist Zoubareff, and later the editor's chair was offered to Mr. Kandratieff, who was unable to accept for want of leisure.

In 1891 Kandratieff lost his only remaining child, a daughter. This so deranged his health that he completely lost his night's sleep, finding rest only towards morning each day. To somewhat fill up the terrible vacancy in his life, he undertook, with his friend Izerguine, the translation into Russian of the French edition of "The Hive and Honey-Bee," of Langstroth-Dadant. At the same time he elaborated a program for a new bee-journal. During each summer he took a trip to foreign countries and became acquainted with Metelli, Dubini, Visconti, Paglia, Barbieri, and Lambertenghi, in Italy; and returning by way of Switzerland he regularly visited Edward Bertrand, with whom he always found a hearty reception and many new ideas on bee-culture. Bertrand approved the idea of this new Russian journal, and in 1892 they issued the first number of the "Messenger of Foreign Apiarian Literature"—Wiestnik Inostranno Literature Ptchevolovstva.

As is often the case when something new appears, the Messenger met many ill-disposed people who affirmed that foreign ideas are of no value to Russia, and that special methods must be created for that country, as if the Russian bees were not the same insect as the bees of other countries. But time smoothed everything; the plan of Kandratieff, of publishing the paper at the low price of one rouble (about 51 cents) and of printing in it all things that were new and worthy of notice in Europe in apiculture, proved to be excellent. The journal had great success; it is now very much read, and its propaganda has had much influence on Russian bee-culture. Many pleasant acknowledgments are received from all parts of the Russian empire. Those letters written mostly by persons who have followed the advice given in that journal, express the hearty thanks of their writers for their leader and guide.

It is especially the Dadant hive and system which Kandratieff recommends in his magazine, showing its advantage over some other methods recommended by opposing apiarists who have their own systems. The result of his constant and indefatigable propaganda concerning this hive, and of the success obtained with it, has been its establishment as the hive the best liked and the most in vogue in Russia.

Kandratieff has put into the hands of his devoted friend, Izerguine, for three years past, the management of the Messenger. He, however, continues to support the journal with his contributions. He has also translated into Russian the "Conduite Du Rucher" of Bertrand, and the pamphlet entitled "The Modified Dadant Hive," also by Bertrand, which is now in its third edition. He has in addition translated the "Memorandum" of the Italian Dubini, and the unedited "Letters of Huber." He has also published the Dubini pamphlet "Honey as Food and Medicine" (20,000 copies), and Prof. Zubarsky's, "The Medicinal Properties of Honey," the latter to the extent of 90,000 copies. Owing to the moderate cost of these two pamphlets they have been so scattered all over Russia that some honey-dealers give them away with the honey they sell.

After all that has been said concerning this worthy bee-master, it goes without saying that the name of Kandratieff will remain connected with the transformation of bee-culture in Russia and its development by rational methods, so we may hope that bee-culture there will again reach to the magnitude it used to have in ancient times when that country exported its bee-products to all countries of occidental Europe.

Queenie Jeanette is the title of a pretty song in sheet music size, written by J. C. Wallenmeyer, a musical bee-keeper. The regular price is 40 cents, but to close out the copies we have left, we will mail them at 20 cents each, as long as they last. Better order at once, if you want a copy of this song.

No. 3.—Practical Lessons for Beginners in Bee-Culture.

BY J. D. GEHRING.

Continued from page 230.)

"WELL, Mr. Bond," I continued, "you notice there is a piece of heavy, strong muslin as a cover on the top of the super resting on the frames of the hive. That cover is necessary because without it the bees would get out into the space under the hive-cover and around the super. Of course, you understand, when there are two or more supers on a hive we put the cover on the topmost. I use muslin instead of oilcloth, because muslin lets the moisture and some of the surplus heat escape, and oilcloth does not."

"Now, before we can do anything inside the hive this super must be removed. I have seen bee-keepers who would first blow smoke under the muslin cover into the super to make the bees go down into the hive, but I don't do that because when driven down they are in the way."

"Well, I declare, if there isn't a swarm coming out yonder?"

With this exclamation I started on the run toward the hive casting the swarm, bidding Mr. Bond to follow me.

Arriving at the hive I stooped over and shoved the entrance-blocks toward each other, thus contracting the entrance-space. Mr. Bond was of course curious to know why I did this, and I explained thus:

"I do this in this case because I don't want the swarm to get out so fast—they were rolling out by the pint, you noticed. The object is this: As there is only a small space for the bees to come out thru, it takes the swarm a long time to get out, and those that are out first get tired flying around. The queen is usually out with the first quarter of the swarm, and is flying around with those that are out, but, as she isn't used to much exercise, she is sooner tired out than the others, and hence, instead of waiting for the rest of the swarm, alights on a convenient branch of a bush or tree to rest, and the swarm clusters there, completely covering the queen. If there is a large bee-space, however, the bees will all get out in about two minutes, and, being fresh on the wing, and excited, they will fly off in a body, sometimes quite a distance away, and then cluster away up in a tall tree, where you get me a long ladder and a rope and a saw, or an ax, to get them."

"Now, watch this swarm," I said to Mr. Bond. "You see they are flying around near the hive as tho they didn't know what to do. They do that because they are waiting for the rest of the swarm to join them. There! they are settling on that apple-tree, on a limb low down. Now, I'll show you how I have a swarm of bees," I said to Mr. Bond, pronouncing the personal pronoun with strong emphasis, to remind him of his way."

"Now, Mr. Bond," I continued, "the first thing in order in this case is to move this brood-chamber far enough away to make room for the hive I'm going to put in its place. First, however, I open it and take the super off. It is nearly full of honey or I would leave it on. You see I figure to economize strength. The fact is, in my case this is necessary because, as you know, I'm not very strong—my left arm is nearly useless for lifting on account of partial paralysis."

"Why do you reverse the hive?" queried Mr. Bond, after we had moved it to its new place.

"Because," I replied, "if I don't do it the entrance would be facing the same way it did before, and thousands of the bees, as they come in from the fields, would enter the old hive. But I don't want them there, but in the hive the swarm is in."

"But we must now hasten to get the new hive in order and put it in position where the old one stood. We can never know how long a swarm will stay where they settle. You see, this is not the usual time of day for bees to swarm. A swarm that will do one thing out of the usual order can't be trusted not to do something else that is unusual."

"Now," I said, when the new hive had been placed, "we will take a look inside and see that everything is in working order. This hive has eight frames in it, you see,

every alternate one filled with three-quarter sheets of comb foundation. The others are empty, because, when the swarm is very large, like the one we are now dealing with, it completely fills the hive. In a short time it becomes so hot inside that, when there are sheets of foundation in each frame, some, and often all of them, get so soft that they collapse to the bottom of the hive. But when only half of the frames are filled with foundation sheets the bees have more room and more air, and the accident mentioned doesn't happen. But now we will get that swarm."

The swarm was secured by standing upon a box, taking a firm hold of the small limb at the end of which most of the bees were clustered, getting hold with my left hand just back of the cluster, and then cutting the limb off carefully with a large and very sharp pocket-knife. Great care had to be taken, of course, not to jar the limb in the act of cutting, and thus dislodge the cluster.

"Now," I said to Mr. Bond, as I was yet standing upon the box with the limb in my hand, "as you are taking practical lessons in bee-keeping, suppose you take hold as near my hand as you can and carry these bees over to the hive. You needn't be afraid if they crawl on your hand, they'll not sting you."

Mr. Bond did as requested, a little timidly, to be sure, but successfully. "Now just lay the limb down carefully in front of the hive, and as close as possible to the entrance, and then watch them run in," I said.

"And is that all there is to it?" ask Mr. Bond, looking surprised, and, I thought, a little disappointed.

"By that you mean, I suppose, that there is much more to it when you have a swarm of bees," I replied. "Well, I have a much more simple and easy way than even this. But I will tell you about it some other time."

"There is an important secret, however, about this swarming business that you ought to know before you have any more swarms in the way you learned of your father. I think if you examine all the hives standing around under trees and hedge fences on your farm you will discover that some of them are empty, and I can explain why:

"When a swarm of bees issues from a hive, and the queen has selected a place, or location, for it to cluster, a lot of bees which we call a 'scouting party,' composed of a hundred or more, immediately leave the cluster to find a new home. This advance party usually goes to the nearest piece of timber-land where they look for, and usually find, a suitable cavity in a tree, which they examine and proceed to clean out, if found large enough. This is known as a fact, because bee-hunters have been misled by such proceedings into believing that a bee-tree had been found."

"One such case occurred in the bee-hunting experience of a brother of mine. On looking up into a tree for signs of bees, he saw a large number flying in and out at a hole in the trunk, as tho busily at work in the usual manner of a colony. He then set to work to mark the tree as his property—or the bees, rather—by cutting the initials of his name and the date of the discovery in the bark of the tree. While thus engaged he suddenly heard a great noise of humming, as of a swarm of bees above him, and looking up he saw a large swarm in the act of entering the hollow in the tree."

"This, and like observations by experienced bee-men, has led to the theory of the 'scouting party,' and also to the belief that when these pioneers have the selected home about ready for occupation they either return to the swarm in a body, or else a detachment only goes back, to escort the swarm to the new home. This is doubtless the reason why a clustered swarm will sometimes very suddenly depart for the woods while the bee-keeper is actually engaged in living it. And, sometimes, such a swarm will leave a beautiful and well-furnished hive soon after being put there."

"O, I know this very much resembles a 'fish-story,'" I said, noticing a skeptical smile on Mr. Bond's face. "But I can give you substantiating facts from my own experience:

"One day last year a neighbor a few blocks away sent word that a swarm of bees had settled on the limb of a peach-tree standing near his woodshed in the back yard, and that if I wanted it I should come and get it. Taking my swarm-box, specially made for such occasions to secure and carry the bees home in, I went over to my neighbor's yard. The swarm was a large one, and hung over the woodshed roof within easy reach. I took my box and limbed upon the roof, and, holding the open end of the box directly under the cluster, I was just in the act of reaching up to give the limb a shake when I heard, directly above my head, a loud buzzing noise as of a small swarm of bees,

I was for the moment greatly puzzled, for the clustering bees had, up to this time, been very quiet, and none had taken wing. I was sure; but, looking upward, I saw flying about the top of the tree in an excited manner, what looked like a small swarm of bees.

"Well, sir, in much less time than it takes to tell it, that swarm of clustering bees detach themselves from the limb and were off, going like a cyclone toward the woods down your way."

(To be continued.)

Criticisms and Suggestions about the Score-Card.

BY FRIEDEMANN GREINER.

I HAVE had some anxiety in regard to what the score-card committee would hatch out, and I am pleased now to find the work of our worthy committee in the shape of the proposed score-card in all its details published on page 166. I suppose the committee was aware how impossible it is to suit the notions of every one, and probably expected their work to be criticised. If I point out some features wherein a change might be an improvement I do so with due respect to the gentlemen of the committee.

On the "General display" I find nothing whatever to change. It is all right.

In the "Single-case" entry, it seems to me too much importance is attached to "attractiveness," giving it 50 points. This would be all right in the "General display," but in the "Single-case" entry it seems "attractiveness" might at least be placed on an equal footing with "quality" and "quantity," if not placed below them in importance. A display we expect to be as attractive as possible, but in a single-case exhibition the superiority of the honey itself should be the governing feature.

The "Bee-entry" paragraph needs, according to my ideas, the greatest modification of any. The committee has overlooked the fact that a colony of bees can not be considered complete, in particular for exhibition, without it contains not only queen and workers, but also drones. The latter have, however, not received any consideration at all. The reason for this is not apparent. The drone is the largest, makes the most noise. He is not very modest, by any means, and is very often around when he is not wanted at all. I wonder the committee could overlook him. Can it be possible the committee gives him the slip purposely? Is not the drone of sufficient importance to deserve consideration? If two nuclei were otherwise perfectly equal, but one of them should contain a few drones I should certainly award the first prize to that one. If both should contain drones, but those of the one were larger, and showed better markings, then that one would be preferred by me.

"Color" and "markings" might be taken as referring to all the bee-individuals, as queen, workers and drones, but it would be generally understood as meaning just the working bees, therefore I believe the drone should be especially mentioned, and would favor the score-card about as follows:

	Color and markings of workers and drones.....	25
	Size of workers and drones.....	20
NUCLEUS	Queen, presence and markings.....	20
OF BEES IN	Drones, presence.....	10
OBSERVATION	Brood, including drone-brood.....	10
	Quietness of bees.....	5
HIVE.	Style of comb.....	5
	Style of hive.....	5

In regard to beeswax there is some uncertainty as to color. It is not fully settled what the color of the wax should be, and it is left to the one acting as judge whether he would give preference to yellow wax or white. As the bees manufacture it, its color may be said to be white; as we manufacture it, it is yellow—lemon-yellow at its best: I would be in favor of yellow as the standard color.

Wax should also have a peculiar aromatic odor. Aroma should be taken into account when judging, and so should have a place on the score-card. I would reduce "color" and "purity"—each given 30 points on the card by five each, and place the gained 10 to the credit of "aroma." True, a judge may act upon his own ideas, but it seems to me it would be advisable to take this point in.

Ontario Co., N. Y.

The Premiums offered this week are well worth working for. Look at them.

Are Bees Necessary to the Complete Fertilization of the Bloom of Fruit-Trees?

BY THADDEUS SMITH.

THE part that bees play in pollinizing fruit-bloom is a subject that has been discussed at various times in the past, and is still made a prominent theme in some bee-papers, and in some of the discussions of bee-keepers' conventions. Claims are made by them that bees are necessary in order to insure a full crop of fruit, but such claims are not substantiated by facts or any positive evidence to sustain them. Bees visit fruit-tree bloom for honey and pollen, and in so doing go from one flower to another and are supposed by some thus to disseminate the pollen that fertilizes the flower. It is a very pretty theory. Bees and flowers! Sounds somewhat poetical, you know. But it lacks the facts to sustain it. It has been asserted so often that many persons have taken it for granted that it is true without investigation, and the cry has been taken up and repeated by writers who know nothing practically about it. But some of our experiment stations and professors of a more investigating mind feel the necessity of having some positive proof of these often repeated assertions, and are making experiments to see if they can find that proof. A report of some of these experiments was recently made by Prof. Lowe to a New York convention of bee-keepers, and an account was given of them in an editorial in *Gleanings in Bee-Culture*. Further on I wish to refer to these experiments more in detail.

There has been some contention between fruit-growers and bee-keepers that has produced an ill-feeling between them, the fruit-growers contending that bees destroy grapes and other fruit by biting holes, and sucking out the juice, leaving the fruit to rot; while bee-keepers claimed that fruit-growers spray their fruit-trees unnecessarily while they are in bloom, thus poisoning their bees. These charges and countercharges have produced a bad feeling between the two classes in some sections, when in reality there is no conflicting interest. The fruit-growers are certainly of benefit to bee-keepers because they increase the area of bee-pasture that supplies the bees with more honey and pollen. Bee-keepers, with less show of reason, are now trying to convince the fruit-men that bees are of great benefit to them, by claiming that a full crop of fruit can not be had without the aid of bees to pollinize the bloom.

I have been both a bee-keeper and a fruit-grower for over 40 years, and have been an enthusiast in both occupations, and have given these matters of contention between the two classes a thorough and impartial investigation, and arrived at conclusions that I believe are just to both parties.

Some 15 or 20 years before the case of Utter vs. Utter was brought for trial in court, I had settled the matter of bees destroying grapes, in my own mind—completely exonerating the bees. I had 30 acres of grapes, and over 40 colonies of bees, and the time came that I found the bees working upon the Delaware and other early grapes in great numbers, and apparently destroying hundreds of pounds. I was greatly perplexed and disliked to give up my bees, but if they were the real culprits I would be compelled to give them up. I did not act hastily in the matter, but set about thoroughly to investigate the subject, and after two or three years I had solved the mystery. I discovered that birds—one bird in particular, the beautiful Baltimore oriole—first punctured the grapes, and the bees gathered only the wasting juices; and further experiments convinced me that bees never attack perfectly sound grapes or other fruit. I also find myself on the side of the bees in the case of spraying fruit-trees while in bloom. I think it is unnecessary to spray while in bloom; and not only that, but it is an injury to the bloom to do so.

But when it comes to the claims of my bee-keeping friends, that no complete pollinizing of fruit-bloom can take place without the intervention of bees, and consequently a full crop of fruit can not be had without bees, I must respectfully differ from them, because I see, year after year, both large and fine crops of fruit, of many varieties, raised without the intervention of bees, in fact where bees are entirely excluded from the bloom by natural causes. It would be unreasonable in me to doubt my own senses of sight and taste to believe that there was anything in such claims of bee-keepers. From my view the claim looks absurd, and I take the position that bees are not necessary to the complete pollinizing of any kind of fruit-bloom, and I think I can prove it. Now "to the law and the testimony," or rather to the facts that ought to convince any unprejudiced mind.

But first I wish to notice the experiments made by Prof.

Lowe and heretofore alluded to. These were made by enveloping trees and parts of trees in a hood made of sheeting in order to exclude bees and all other insects while the trees were in bloom. The trees so sheeted were found to set much less fruit than those left in their natural condition. It would have been very unreasonable to have expected any other result from this experiment. The trees so treated were placed in a very unnatural condition. The free circulation of the air was excluded. The vivifying rays of the sun, so necessary to the growth and development of the average plant life, was excluded, and light, tho not entirely excluded, was greatly obscured, all of which Nature provides most bountifully for the perfect normal development of fruit. The unnatural heat in that hood when the sun was shining upon it, without the circulation of air inside, may alone have been sufficient to have destroyed the delicate germ of reproduction, or prevented the grains of pollen from ripening sufficiently to perform its functions. The sun shining upon the outside of this hood, with no air in circulation within it, would produce an unnatural heat inside, enough to injure the undeveloped pollen and pistils; and these conditions would render the experiment abortive. In keeping the bees and other insects out, the wind was also kept out, and this is the main cause of the unreliability of this experiment. No one will deny that the wind plays a most important part in pollinizing flowers not only of fruit-trees, but of all the vegetable kingdom, many of which are never visited by insects of any kind. The wind loosens the pollen from the stamens and sets it in motion, and the invisible particles are wafted hither and thither by every breeze that blows, bringing some of these particles in contact with the pistils of the flowers, and in some wonderfully inscrutable way causing them to produce fruit and propagate the species. The wind is Nature's agent to disseminate pollen, and every experiment that excludes it is unreliable.

The All-wise God who made all things and provided for their continuance on earth, and said that there should be seed-time and harvest as long as the world stands, did not leave the fulfillment of this promise to depend upon the uncertainty of bees and other insects, but chose a more universal and surer medium to perform the important work of keeping up the vegetable kingdom—of producing fruit.

In some countries there are no bees, as in North America before the white men came, and there are now places in this country where there are no bees, and in many of these places the circumstances and surroundings are such that other insects can not do this work. It is to some of these places where there are no bees, to which I wish to call attention, and give some facts that well sustain my position.

I live on an island in Lake Erie, and near by me are several smaller islands upon which no bees are kept, and they being from six to ten miles by water from any place where there are bees, no bees ever visit them. These islands are all noted for their production of fruit. Middle Bass Island is just across the international boundary line between Canada and the United States, and is one of the largest of these islands where there are no bees, and the whole island is devoted to successful fruit-culture. Upon this island lives a friend, Mr. George M. High, one of the most successful fruit-growers in the State of Ohio, who excels both in quantity and quality of his fruit; growing successfully nearly every variety of fruit that can be grown in this latitude. Several years ago I asked Mr. High to join me in investigations by making daily observations when his trees were in bloom, to see if they were visited by honey-bees and other insects, and to what extent by other insects. This he readily consented to do, becoming much interested in the matter himself. His reports were that he had never seen a honey-bee in his orchard, saw a few bumble-bees but they were not enough to visit one fruit-bloom in ten thousand; also saw a few small "other insects" on the bloom.

These observations have continued for several years with the same result. I visit Mr. High about twice a year—when fruit-trees are in bloom and when the fruit is ripe—and I know what he and his neighbors are doing in the fruit-line. Their trees set fruit so abundantly that peaches and plums have always to be thinned out, and they have surer annual crops than any other place that I know of *all without bees*; and these facts ought to convince the most skeptical, and those who are most anxiously interested, to establish the contrary that bees are *not necessary* to pollinize the bloom of fruit-trees.

I am aware that I may be confronted with the assertion, or argument, if you choose so to call it, that other

insects were or might have been the means of pollinizing these island fruit-trees so perfectly. For argument's sake I grant this, and let us see what it proves. If anything it proves that bees are *unnecessary*, as other insects can insure good crops of fruit without bees. So the advocates of the importance of bees do not get much comfort from that. But I deny that other insects did it, and I propose to prove it.

The first witness that I shall introduce is Mr. O. L. Hershisier, one of the witnesses who gave his evidence at the convention of the New York State Association of Bee-Keepers on the side of those who were trying to prove that bees were necessary to pollinization, etc. I quote from the proceedings of that New York convention as reported in an editorial in *Gleanings in Bee-Culture*.

"When the professor [Lowe] was asked how much of this pollination was attributable to bees, and how much to other insects, he said he could not tell; but Mr. O. L. Hershisier in referring to a similar set of experiments made some years ago at the Michigan Agricultural College showing the same results, said the bees were altogether the earliest insects out; that at the time the average fruit-tree is in bloom it is too early in the spring for other insects to be of any value. In his opinion the covering of the limbs or the covering of the whole tree, as explained by Prof. Lowe, showed clearly that the bees, and they alone, did the mixing of the pollen."

Notice Mr. H's evidence as to the fact that "*it is too early in the spring for other insects to be of any value*;" and this corresponds exactly with Mr. High's observation on Middle Bass Island, and with my own, made repeatedly, here on Pelee Island. When these three witnesses agree so well in their evidence, that "there are not insects enough out at the time of the blossoming of the average fruit-tree to be of any value" in pollinizing, then it ought to be sufficient to establish that fact beyond question, and put a quietus to the "other insect" theory.

As to Mr. H's "opinion," or his conclusion from Mr. Lowe's experiments that "*the bees, and they alone, did the mixing of the pollen*," I am willing to leave it for what it is worth, as from the facts already given it can not be worth much. He reminds me of some other evidence and conclusions that I once saw in print on this subject. This writer said that he knew the bees were of great benefit to fruit-growers because he had some pear-trees near his apiary, and the sides of the trees next to his bees bore a good crop of fruit while the opposite side bore scarcely any. Comment is unnecessary.

There are a number of other points on this subject that I would like to notice, but fear that I am already too long. But I will say, if there are experimenters and professors who really desire to give this matter an impartial investigation, I should be pleased to have them come here and I will take pleasure in doing all I can to aid them.

Pelee Island, Ontario, Canada.

Queens Only One Year Old for Comb Honey.

BY G. M. DOOLITTLE.

A CORRESPONDENT writes as follows: I have decided that every colony that is intended to be run for comb honey during 1902 must contain a queen of this year's rearing. I desire good queens, that my stock may not deteriorate. In view of the foregoing, what plan can I follow in order to produce the best results for a series of years? Please tell me thru the columns of the *American Bee Journal*."

In answering this, I must say I can not conceive what line of argument could have been used to bring the questioner to a decision that he would not allow a queen over a year old in his apiary, which was to be run for comb honey, and can not help thinking that when his experience accumulates, he will find that his decision is not well-founded; for queens which are in their second year do fully as good work as younger ones, where the colony is worked for comb honey, and often are equally good the third and fourth year. Those who have read the *Canadian Bee Journal* for February, 1901, and treasured up what is found there about queens, will have "a feast of good things" to revel in for some time to come, along this matter of queen-rearing. There, Mr. J. B. Hall, than whom the world can not boast of a greater apiarist or more practical comb-honey producer, has things to say about prolific queens which it would be well for all those to heed who have considered that prolificness in queens was the *ne plus ultra*. Among other things he said was this:

"I want longevity in my bees; I want that first and foremost; that is why I don't want to replace my queens every year, because if I do I must kill them, and I don't know what to kill. If I keep them three or four years and they have done good work for four years, wintered well

given me comb honey and in good shape, that is the kind of queens that I want to rear others from." And in reading that, from the foremost practical comb-honey producer of the world, I said right out loud, "Amen." Working along that line means a constant improvement in our bees, while resolving that each colony must have a new queen every year, has not a single element of improvement in the whole "shooting match." Besides the above I find, as a rule, that the bees will supersede their own queens as soon as they begin to fail to any appreciable extent; and when the bees undertake this work it is done much more satisfactorily, all things considered, than it is when the apiarist attempts to say, "This shall be," or "This shall not be."

But if our correspondent thinks he must have his own way, then there probably is no better plan than to follow what is given in "Scientific Queen-Rearing," or that given by W. H. Pridgen, during 1900, in the bee-papers. If you think this too much bother, or consider it "fussy," as some claim, then you can rear pretty good queens in this way:

Kill the old queen and let each colony rear one from her brood. In five days from the time you killed the old queen, open the hive and look for queen-cells. In doing this it is well to shake the bees off the combs so that the cells can easily be discovered. If they are found capt at this time they should be destroyed, as they will contain larvae that are too old to make good queens. Bees do not cap over a cell containing a good queen-larva, as a rule, in less than six days from the time the mother queen is removed. The reason for this lies in the fact that bees rarely miss their queen to a sufficient extent to start cells in less than from two to two and one-half days after her removal; and if you find cells sealed over on the fifth day after the removal of the old (or mother) queen, you may know that the larva in said capt cell must have been three to three and a half days old when the bees undertook to change it to a queen. All queen-rearers agree that larvae two days old and under give the best queens, and that a larva older than three days should never be used under any circumstances, if we would have queens which can to any extent be called good. Of course, the colony is to be well fed, if no honey is coming in from the fields, until the sixth day, or till all cells are capt over.

Onondaga Co., N. Y.

Questions and Answers.

CONDUCTED BY

DR. C. C. MILLER, Marengo, Ill.

(The Questions may be mailed to the Bee Journal office, or to Dr. Miller direct, when he will answer them here. Please do not ask the Doctor to send answers by mail.—EDITOR.)

Getting Increase—Kind of Bees.

1. What is the best way to increase rapidly the number of colonies for a beginner? I have six strong and one weak colony that I shall have to feed. I am giving partly filled sections to this one now. I would like to increase to 60, but do not count on getting any surplus honey to sell. This is a fair location for honey. I had one strong colony that put 60 pounds of honey in sections; the other one did not do much but swarm; I got 5 natural swarms from it. The 4 will winter well. The honey sources are willow, elm, soft maple, sugar maple, basswood, red and black raspberries in abundance, gooseberry, plum, apple, peach, cherry, and a few pears. The fall bloom is where we get most of our surplus, such as buckwheat, goldenrod, and fireweed. You see I have a steady flow most of the summer, which is necessary for you to know in order to give your opinion.

I do not know what my bees are. I will Italianize the whole in a little while, or as soon as they begin flying well. I bought 3 queens last September, and made a success of all, so I have only 4 more to make all of an improved strain, which I think will be the best way to start.

2. Which strain is the better for extracted honey, the 5 or 3 banded?

3. Could you tell me what breed mine are? They have 5 bands, are larger than Italians, and longer, are ugly, and rush about the hive as soon as opened, and sting anything that comes along quickly, and will only retreat before a

cloud of smoke. In handling supers it keeps one using the smoker to do anything with them. They are good workers, and if they were gentle I would not change.

MICHIGAN.

ANSWERS.—1. If you do anything in the way of rapid increase, the first thing is to get a text-book and become familiar with general principles and with the different ways of increase therein. My advice to a beginner desirous of increasing from 7 to 60 would be—don't. You might without such a great deal of trouble get 60 started, and then you might with less trouble have all dead before Christmas. The wiser plan will be not to set any such limit, but to work on safe ground and increase just what you can safely, whether it be to 16 or 60. Take the nucleus plan, and having used one or two colonies to start nuclei, draw from the others to build them up, but do not allow yourself in any case to draw from a colony so as to reduce it to less than four frames of brood. Then you can start others, and as fast as a nucleus becomes strong enough it can do its part toward helping, only keep in mind all the time that in drawing you must not reduce to less than four frames of brood. In this way you will not be caught with a lot of weaklings, but can close up any time when the weather threatens to close up. Of course, with such a long season as you seem to have you may be able to reach the goal you have set, but don't count on going beyond just what you can safely do.

2. Some colonies of one kind are best, and again some of the other.

3. Very likely they are Italians, and very likely if you compare carefully with other bees of the same age, you will find them of the same size as other Italians. Some of the 5-banded Italians are reported as cross, and others as gentle.

Queen Flying in March.

March 24th my bees had a fine flight, it being the first warm day since the holidays. While watching them just at noon I saw a queen come out and fly away, but return in 15 or 20 minutes. This was repeated three or four times while I was watching them. The colony is strong in bees, and was working nicely carrying in pollen. Now, was that a young queen trying to mate? If so, why did the bees supersede the old queen so early when there are no drones? If the colony became queenless in the winter where did they get the egg to rear the queen? It has been so cold since that I can't look thru the hive. It has been too cold for bees to fly ever since. I have been keeping bees since the spring of 1881, but this is something new to me. INDIANA.

ANSWER.—It may be that the young queen was reared last fall late and failed to mate, and she may yet be all right. At any rate such cases have been reported in which the queens turned out well.

Alfalfa Not Recommended for South Carolina.

I have about 20 colonies of bees at home, and on another farm 3 miles away. I wish to try, on a small scale, the best clover for hay and also for bees. A friend of mine tells me that while he was in the distant West he noticed bees doing well on alfalfa, and says its hay quality surpasses all he knows of. But, of course, he knows nothing as to its being adapted to our climate. Will alfalfa do well here? Is it used to any extent by bees? How much per acre, and at what season can I with reasonable certainty sow the seed? Will the alfalfa grow wild? I think I have heard that bees may not look for help from alfalfa for two or three years after sowing. SOUTH CAROLINA.

ANSWER.—As far east as Illinois alfalfa will grow, but seems to be of no value for bees, altho in the States farther west it is one of the best honey-plants. It is not likely that it would be of any value in South Carolina. Sweet clover, alsike, and crimson clover, are the things for you to try.

When and How to Form Nuclei.

1. I have studied three bee-papers all the winter, besides several bee-books, but so many plans only confuse me. What time (please give month) and how shall I form nuclei for increase, so as not to interfere with some surplus honey?

2. Will taking two frames of brood and bees before time for white clover weaken the colony so they will not store any honey?

I opened a hive the other day, and very much to my

surprise discovered a clipt queen. How she came there I do not know, but I think she is the premium queen I had of Dr. Miller last year, which I thought the bees killed while robbing. I put the empty combs (as I thought) in this hive, and must have taken the queen without knowing it. Anyhow, she has a nice lot of Italian bees. SUBSCRIBER.

ANSWERS.—1. In forming nuclei, don't go by the month, but by the posies and the strength of colonies, altho June will probably be the month. When the first white clover blossom is seen, it will be early enough, altho you might commence a little sooner if colonies are very strong, and in any case not till they are strong. One way to form a nucleus is to take three frames of brood with adhering bees and pen them in a hive bee-tight, plugging up the entrance by cramming into it green leaves. Not sooner than the next day at noon open the entrance, and they will be likely to stay. It is easier to get queenless bees to stay in a new place. Try this. Take the colony that has your best queen, and if it is not strong make it strong by giving it frames of brood a week before you operate upon it. Then take from it two frames of brood with adhering bees and the queen, and put them in a hive on a new stand. Not less than seven and not more than nine days later, form your nuclei by giving each three frames of brood with bees, putting one of the nuclei where the nucleus with the queen has been for the past week, and putting the hive with the queen back on the old stand. See that each nucleus has two or more good queen-cells near the center, so there will be no danger of chilling.

2. No; from a strong colony you might take more than that and still get a fair crop. But taking before white clover is much more expensive than taking later. In a good season it would hurt less to take two frames every 10 days if you wait till they are storing well on clover.

Feeding Sorghum Molasses.

What would you say about feeding bees sorghum molasses (that is, molasses made from cane)? Do you think it is injurious to the bees?

I am keeping bees for another man, on shares. I just began last fall, but I have kept from one to five colonies of my own for five years. Last year was a total failure here, no clover at all, but the prospects are good for this year. Clover is coming on in fine shape. Bees are flying nearly every day, and are working on elm. I don't know what they get. MISSOURI.

ANSWER.—It would not do to feed sorghum molasses for winter food, but when bees are flying daily in the spring they may be fed sorghum or anything else they will take that is not actually poisonous.

Inverting to Destroy Queen-Cells.

I have nearly decided to adopt the Heddon hive in my future plans for increase in the apiary, and I have seen it stated by Mr. Heddon that a sure way of destroying queen-cells in that hive is simply to invert the section and the bees will destroy all queen-cells. Can you tell me if it is a fact? Have you ever given the Heddon hive a trial? As hunting for queen-cells forms no inconsiderable part of a day's work in the apiary, a plan that will destroy those we do not want as easily as reported, is very desirable, if true. And as it is scarcely practicable with the suspended frame, I am ready to adopt an invertible hive, if it will do the business. "RIP VAN WINKLE."

ANSWER.—A few years ago it was thought by some that inverting queen-cells would lead to their destruction by the bees, but after further trial the plan has been found to be altogether unreliable. I have never tried the Heddon hive.

Swarming.

1. When a prime swarm issues does the queen always come out about the last of all, and first when an after-swarm issues?

2. In swarming-time, when a colony seems to be about ready to swarm, how would it work to place a cage in front of the hive with a bee-escape from hive to cage, and another from the cage to another hive standing at one side with full sheets of foundation? And about the second day put a queen in the new hive, and leave them arranged in that

way for several days? Would I succeed in running most of the workers from the old hive into the new? If so, would they accept the new queen and go to work all right? Would the queen and bees left in the old hive give up the idea of swarming? IOWA.

ANSWERS.—1. No fixt rule about it. The queen may be among the first or among the last in either case; but she is more likely to be among the last in a prime swarm and among the first in an after-swarm. But as to the after-swarm I have had very little chance for observation, and am ready to be corrected.

2. Sorry to say I don't believe it would work at all; but having never tried it I may be mistaken. My guess would be that it would fail in each particular.

Beet-Sugar Factory's Effect on Bees.

I attended a beet-sugar meeting the other night, and in discussing the matter a man from Rockyford said that beekeepers would have to move their bees a mile or so from the factory, as acids and chemicals were used there that would kill the bees. It was not a bee-meeting, so I could not discuss this subject, but I would like to have you tell us thru the columns of the American Bee Journal whether or not this is true. It is a matter of great importance to beekeepers out West. COLORADO.

ANSWER.—I don't know whether a beet-sugar factory is a bad thing for bees or not. Some subscribers must be living within a mile of one of these factories; will they please tell us?

The "Old Reliable" seen thru New and Unreliable Glasses.
By E. E. HASTY, Sta. B Rural, Toledo, O.

EXTRACTING HONEY.

Yes, sir-ee, Mr. Aikin, propolis will go to the bottom where it can't do anything else than burn on. Burrs and all sorts of scrapings with propolis in should go thru the solar extractor the first thing. Then, as after transactions, remelt the wax, if necessary, and re-treat the waste cake. And—another yes, sir-ee—the stubbornness with which cold comb honey refuses to take heat is quite incomprehensible to the beginner in bee-practice. Sometimes when in a hurry one can run the combs thru the extractor and throw out part of the honey, then hang them up in a warm atmosphere an hour or two, then run them thru again. But don't hang the combs very close together, even if three-fourths empty. The idea of a large gravitating tank with chance to heat it underneath is an important idea. Two such tanks, so one could be undisturbed while the other was being filled, would seem to be the ideal arrangement. And the whole article on page 167 is one of the very best Mr. Aikin has given us.

QUELLING ROBBER-BEES WITH GUNPOWDER.

"And sometimes civilization does git forrard
Upon a powder cart."

We know that; but most of us never thought of civilizing robber-bees with gunpowder. No doubt it would "hist 'em" if the charge was big enough. And any very offensive smell may discourage them if they are only fussing around and not getting much. Some brother who has a too-well-worn hat, present it to Peacemaker as a premium for his contribution. Page 175.

THAT GENEROUS DOG AND BEE-STINGS.

That was an all-right and head-level sort of dog, on page 175, that wanted to share with his young master the bliss of communion with bumble-bees. Masters like the aforesaid should not object to tasting of dishes which they have cookt.

DOLLAR-A-POUND HONEY EXCLUDING BEES.

Honey at a dollar a pound is rather dear. But health and fun at a dollar a pound—well, most of us would find purchase a little occasionally. So let Mr. Metcalf go on hunting his dollar-a-pound wild honey. Page 180.

So Chicago can get along nicely without a bee-exclusion

act. But ever and anon some little village (nothing else on its cosmo-embracing mind) finds it necessary to put them out. Page 179.

DRONES AND WORKERS.

I hardly think Mr. C. P. Dadant needs to cavil about a drone eating as much as two workers. Sorry I haven't the exact weight of drones at hand—but all similar objects are to each other as their cubes. So for workers it should be $5 \times 5 \times 5 = 125$; and for drones $4 \times 4 \times 4 = 64$. As the drone's shape is somewhat blunter, it should take somewhat more than 125 workers to equal 64 drones in bulk. Why not expect them to eat accordingly? Again, the drone probably eats all he can, while the workers never do except in rushing times. If Mr. D. is right, that the drone's bulk is only a half more than the worker's, then much of the above falls to the ground.

* The Home Circle. *

Conducted by Prof. A. J. Cook, Claremont, Calif.

SUNSHINE IN THE HOME.

How few of us understand what sunshine has done for the world. Except for the blessed beams which come with their warmth of light, we could have no vegetable growth. The plants need the sunlight to change the carbon dioxide which they inhale from the air, and the water which comes up to them from the roots into the starch, sugar and oils which are to nourish them and to feed their tissues. Indeed, we owe to the sunshine the great coal-beds which make us so rich as a nation, and which, of themselves, contribute so largely to the comfort of so many of our home circles.

Sunshine in the home is as great a factor in supplying its best fruits as it is in the world about us in building up the great plant portion of the earth. Some years since, a man by the name of Alexis St. Martin, received a gunshot wound over the upper part of his abdomen. The healing was imperfect and left a flap which opened into the stomach. Thus, there was formed a sort of a door so that any observer could not only look into the stomach and see its condition but could also reach in and withdraw the ingesta so as to note any time just the condition of digestion. Some very interesting facts were observed. St. Martin was taken around to various of the medical colleges that the students might have the benefit of direct observation regarding digestion. Students are not always considerate and thus St. Martin was often vexed by them. At times he became very irritable and peevish. With age he became so susceptible to outward impressions that it was very easy to affect his temper. He could readily be made either angry or happy at the will of those who held him in charge. It was found that if he was seriously irritated, immediately after eating a full meal, that the stomach remained pallid, showing that the circulation was held in abeyance, the gastric juice or digestive fluid failed to appear in the stomach, and thus there was an almost total failure of the food to digest. On the other hand, if he was in merry mood, the stomach flushed up as the blood coursed thru the capillary circulation, the digestive juices were poured out generously, and the food was soon liquefied, absorbed into the blood, and hastened on to the tissues to help on the work of assimilation.

Here, then, we had a very graphic illustration of what many of us have proved in our own experience. How often has the letter bearing sad tidings, or the evil news told to us just after meal-taking, seemed to stop entirely the wheels of digestion. Often sudden grief of this kind has so checked the machinery of digestion as to give a fatal shock to the system. It is now a well-known physiological fact that any thing which disturbs the mind is a serious break upon all the bodily functions. With mental depression, the heart beats more slowly, the lungs fill less frequently, all the secretions are poured out with languor, and the whole body seems to call a halt. It is no wonder, then, that so important a part of our functional activities as that of digestion should be one of the most ready respondents to this evil effect of bad news.

We see, then, how important it is, if we would maintain health, that we should bring great floods of sunshine into the

home, and should keep from it everything that incites worry or brings displeasure.

It is specially desirable that this matter of sunshine should never be lost sight of at meal-time. Anything that makes the table look more beautiful, as the neat and orderly arrangement of dishes and viands, or the vase of flowers, contributes not only to good digestion, but as surely to good health and long life. We are often urged to eat slowly that the victuals may be more thoroughly masticated and digestion hastened. This is certainly excellent advice. But the long sitting at the table, and the happy disposition of each person in the home to do all possible to make the meal—*I wish I might say hour* of meal-taking, an hour so full of glee that it will brighten all the other hours of the day, is doing more than they know to keep dread disease from the household. Is it Shakespeare who says, "pleasure physics pain," or something to that effect. *I wish I could say something in these talks on the home circle to brighten all the homes of the land, for I would in so doing add not only greatly to the health and vigor of all our readers, but would also do very much to make the work of life much more effective.*

There is another consideration in reference to this matter which is well worth our thought. Discomfort in itself is very apt to breed the sullen disposition and the irritable temper. From what I have said above, these induce dyspepsia and ill-health. These further build on to the discomfort, which adds again to impede digestion, and thus we have a fearful compound interest which will almost require a miracle to prevent serious disaster.

We often hear it said that worry hurts worse and kills more than does work. This is certainly true, and is easily explained from what has been said above. Surely, then, we make no mistake when we do our utmost to flood the home circle with brightest sunshine. The kind word, the thoughtful act, and the loving sympathy, not only give a foretaste of heaven in our homes, but they tend more than anything else to fence off disease and sickness, and to carry youth into old age. If we could do anything to secure such homes everywhere in our country, we would do that which would be greater with promise for the future of our good land than does even the wondrous prosperity which I referred to in my last article. A country full of bright, sunny homes would also be great in patriotism, and would ever be invincible against any foe that might dare to cross its borders.

NURSING IN THE HOME.

I am also minded to say a few words regarding nursing. One has only to be sick and in bed a few days to appreciate the kind ministrations of the loving hands and hearts that do so much to rob even sickness of its terrors, and so much to drive the unwelcome visitor away. It is often said, and I am sure with entire truth, that, of the two, the good nurse is of more value than even the good doctor. We know of a certainty that medicine at the best is only a minor aid in the work of recovering lost health. Very likely many times the medicine does more harm than good. We can never say the same of the good, thoughtful nurse. I have often thought that were I a girl or young woman, and time would permit, I should take the training necessary to make a first-class nurse even tho' I might never wish to make nursing a profession. It is certainly well for every young woman to be fortified by having some business which in case of need would make her independent. There are a few things that woman is preeminently qualified to do. She alone can make the beautiful home; she alone can attain highest excellence in teaching children; she alone can reach the highest attainment as the nurse. Like the good musician, so, too, the good nurse, wherever her lot may be cast, will never find her skill and ability begging opportunities to make themselves felt and useful.

The first thing the good nurse will look to is such thoughtful care and attention that the patient can not have even the slightest worry over the closing of a window, the neatness of the room, the taking of medicine, etc. Every need and requirement will be foreseen and met with such promptness that the patient will have no worry at all. Quiet in the room and about the house, especially in a case where the nerves are involved, will be insisted upon by the good nurse. Inquiring friends will be courteously thanked for their thoughtfulness in calling and the hope expressed that the sick one will be able very soon to see them. No pains will be spared to make the sick one in the highest degree comfortable. Shaking up of the pillows, frequent arrangement of the bed-clothes, and the oft-repeated bathing of the face and hands, especially in the case of fevers, will never be omitted. Perhaps the most important thing of all, and we may say the hardest thing, for the nurse is apt to become very tired and sleepy, is that she

Langstroth on... The Honey-Bee

Revised by Dadant—1900 Edition.

This is one of the standard books on bee-culture, and ought to be in the library of every bee-keeper. It is bound substantially in cloth, and contains over 500 pages, being revised by those large, practical bee-keepers, so well-known to all the readers of the American Bee Journal—Chas. Dadant & Son.

Each subject is clearly and thoroly explained, so that by following the instructions of this book one cannot fail to be wonderfully helpt on the way to success with bees.

The book we mail for \$1.25, or club it with the American Bee Journal for one year—both for \$1.75; or, we will mail it as a premium for sending us **THREE NEW** subscribers to the Bee Journal for one year, with \$3.00.

This is a splendid chance to get a grand bee-book for a very little money or work.

should always look happy and cheerful. The best medicine that the sick one can receive is great allopathic doses of encouragement. Indeed, the cheer that the doctor's visit gives is usually more potent than the medicine he leaves. We see, then, that the nurse whose face is ever full of sunshine, and whose very mien and carriage brings courage and hopefulness, will be one of the most health agents in bringing back lost health and vigor.

MEDICINES PARTICULARLY THE PATENT KINDS.

There are a few things that the sick person can never afford to do. I refer especially to the use of patent medicines. Dr. Oliver Wendell Holmes, so long a favorite lecturer in the Harvard Medical College, made very witty and wise suggestions. One of his telling remarks that I remember is as follows:

"It would be a splendid thing if all the medicine in the world were thrown into the sea, but it would be awful on the fish."

I presume he was wholly right. I know he would have been if he had the word "patent" placed before medicine. Perfection is not of this world. Yet as we all know, patent medicines will cure everything! This one thing ought to condemn them. How utterly irrational is the whole scheme of patent medicines. We know that even the wisest and most experienced physicians usually find it difficult to diagnose diseases. We also know that medicines given under the best direction, as Dr. Holmes' witicism suggests, are of doubtful use. Patent medicines to be rational at all must cure everything, which is surely impossible and absurd. The newspaper advertisements show plainly that patent medicines are gulped down by the car-load. Is there anything that proves more surely the gullibility and readiness of our people to be hoaxed and defrauded than the wholesale consumption of these vile compounds? I hope all of our home circles will see to it that all of these quack remedies are forever banished from their households. If we must take medicine—it is often wiser to touch none of it—let us only use it at the suggestion and under the direction of the best medical advice we can secure.

THE AMERICAN FRUIT AND VEGETABLE JOURNAL, which we have been offering in connection with the American Bee Journal, has been sold to the Farm, Field and Fireside, of Chicago, and will be published in connection with the monthly edition of that excellent farm journal. So those of our readers who were getting the first-named paper will not be losing anything by the consolidation.

Sowing Cleome Seed.—In reply to our request last week about sowing cleome seed, W. Cartwright, of Hardin Co., Iowa, says:

"I will grow and mature in the fall or spring. If I wanted to put it on cultivated land I would sow in the spring and harrow it in. It will reseed itself afterward. Don't sow it on wet land."

For Sale 10 COLONIES OF BEES in eight-frame dovetailed hives, at \$2.50 per colony. My bees are healthy, there never having been any disease among them. **CHAS. SECKMAN,** Shipping-point, Lincoln, Saltfitt, Nebr.

The Bee-Keeper's Guide;

Or, Manual of the Apiary.

—BY—
PROF. A. J. COOK.

460 Pages—16th (1899) Edition—18th Thousand—\$1.25 postpaid.

A description of the book here is quite unnecessary—it is simply the most complete scientific and practical bee-book published to-day. Fully illustrated, and all written in the most fascinating style. The author is also too well-known to the whole bee world to require any introduction. No bee-keeper is fully equipd, or his library complete, without **THE BEE-KEEPER'S GUIDE**.

This 16th and latest edition of Prof. Cook's magnificent book of 460 pages, in neat and substantial cloth binding, we propose to give away to our present subscribers, for the work of getting NEW subscribers for the American Bee Journal.

Given for TWO New Subscribers.

The following offer is made to PRESENT subscribers only, and no premium is also given to the two NEW subscribers—simply the Bee Journal for one year:

Send us TWO NEW SUBSCRIBERS to the Bee Journal (with \$2.00), and we will mail you a copy of Prof. Cook's book FREE as a premium. Prof. Cook's book alone sent for \$1.25, or we club it with the Bee Journal for a year—both for only \$1.75. But surely anybody can get only TWO new subscribers to the Bee Journal for a year, and thus get the book as a premium. Let every body try for it. Will YOU have one?

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

THE RUMELY

TRACTION ENGINES

Should you be seeking the best thing in traction, portable and semi-portable engines, we have what you want. They are ideal for threshing, drilling wells, cutting and grinding feed, running saw mills, pumping water—anything requiring power. We have them
From 8 to 20 H. P.

They all excel as quick, easy steamers, require little fuel, remove dirt, are strong, simple and durable. All boilers made of 60,000 lbs tensile strength steel plate. Fire boxes surrounded with water. Blast, Threshers, Horse Powers and Saw Mills. All for sale, delivered, or on our illustrated catalogue. Ask for it. Mailed free.

LIKE A SORE THUMB.

Our low prices and our **Ten Days Trial** plan are "forever in the way" of the local dealer. He doesn't like us—naturally—because we let our customers take a vehicle and use it 10 days before deciding whether they will keep it or not, and because we sell you better goods for 1 ss money than he possibly can. There are two or three profits on the goods he sells—the dealer's, the jobber's, the manufacturer's. We make our own goods and add but one small profit. In style, finish and material you will find the equal of our vehicles for the money anywhere.

Send for big, free catalogue and particulars of our 10 days trial plan. We make harness too.

KALAMAZOO CARRIAGE AND HARNESS CO., Box 53, Kalamazoo, Mich

MADE TO ORDER.

Bingham Brass Smokers

Made of sheet brass, which does not rust or burn out; should last a lifetime. You need one, but they cost 25 cts. more than tin of the same size. The little open cut shows our brass hinge put on the 3 larger sizes. No wonder Bingham's 4-inch smoke-engine goes without puffing, and does not drop ink drops. The perforated steel fire-gate has 31 holes to air the fuel and support the fire.

Heavy tin smoke-engine, 4-inch store, per mail, \$1.50; 3½-inch, \$1.10; 3-inch, \$1.00; 2½-inch, 90c; 2-inch, 65c. Bingham smokers are the origin-als, and have all the improvements, and have been the standard of excellence for 22 years. Only 3 larger ones brass.

BIRNHAMWOOD, WIS., April 10, 1901.

DEAR SIR:—Please send per mail one 3½-inch brass smoker. A decade's experience has convinced me that the Bingham is the best. Respectfully, M. P. CADY.

T. F. BINGHAM, FARWELL, MICH.

BINGHAM SMOKER.

DEAR SIR:—Inclosed find \$1.75. Please send one brass smoke engine. I have one already. It is the best smoker I ever used.

Truly yours,
HENRY SCHMIDT, Hutto, TEX.

Bringing in Pollen—White Clover.

My bees are still packed as for winter, but I think I shall unpack them soon. They were bringing in pollen on Easter Sunday for the first time in the new century. White clover has come thru the winter in fine condition, and I look for a good honey-year.

H. W. CONGDON.

Hardin Co., Iowa, April 10.

Cause of Bees Dying.

In the answer to West Virginia on page 201 Dr. Miller says: "It is painful to say I don't know." I would like to suggest that variable temperature combined with inferior stores and the long confinement may have had something to do with the matter. The mercury ranged from zero to 40 degrees above, several times within one week during the past winter. My bees spotted the hives and the tops of the frames the worst I have ever known them to do in 10 years of bee-keeping.

J. J. STALNAKER.

Braxton Co., W. Va., April 5.

Loss 15 per Cent—Death of a War Veteran.

My bees are not wintering in good condition. My loss will be about 15 percent, all owing to the fact that I was not thoro in preparing them for winter. We had sickness in our home and the bees were not look after as well as they should have been. We laid my father away to rest on March 25th, after having suffered for over a year with progressive paralysis. He was a war veteran, belonging to Company B, 75th New York Volunteers.

CALXOS VAN BLARICUM.

Calhoun Co., Mich., March 30.

Wintered Well.

I took my bees out of the cellar yesterday morning and they had a good flight. I put 41 colonies into the cellar last fall, and was lucky enough to take 40 out yesterday, which beats my record of the two preceding years very much indeed. However, I have always lost some in the spring after they were placed on the summer stands, and I presume the present season will be no exception to the rule.

COOK CO., Ill., April 2. C. H. MCNEIL.

A Report from Canada.

I put 116 colonies into the cellar early last November, and they are there yet. Everything is still fairly good, so I do not know when I will be able to put them out, nor what my luck will be when I do. Three very fine ones that I had set to one side are in fine condition, and will come thru in good shape, so I am hopeful for the rest.

A. BOOMER.

Ontario, Canada, April 5.

Wintered in the Cellar.

The bees are still in the cellar, and "roaring" to get out, but the weather is unfit. Cold and high winds, rain, sleet and snow alternating, make it unsafe. They were put into the cellar Nov. 8th. Ten of the colonies have been confined since that time, but the rest (26 colonies) were given a flight in February. Up to March 7th none showed any signs of dysentery. March 15th four of the 10 that had not been taken out were spotting the hive-entrances and crawling about it, and perhaps a gallon and a half of dead bees were on the cellar-bottom. A week later all 10 of the hives were spotted, and to-day about half of them that were given a flight in February have their hives spotted and the cellar-floor is covered with dead bees, making fully a half bushel from the 26 colonies since Nov. 8th. The tem-

perature has not been lower than 45 degrees or more than 18 degrees all winter. The covers are sealed down, bottoms the deep side Danzeubaker in most cases; others have an inch block under them. Most colonies are clustered below the bottom-bars, some being on the floor of the hive, and others hanging out of the entrance, as if preparing to swarm.

I would venture to guess that a pretty good-sized swarm was in the air during the few minutes I was in the cellar. I made a hasty survey of matters, and "closed up," concluding to give them their liberty the first day the weather would permit.

We used the last section of our 1900 crop of honey at dinner to-day. It is a regular dish at our house, and no unpleasant results have come of it as yet.

Success to the American Bee Journal.
Sioux Co., Iowa, April 1. F. W. HALL.

1900 a Dry Year—Prospects Fair.

My bees began carrying in pollen about April 2d. It is cold and windy, and we have just had 4 days of rain, so the bees have not been out.

The wind on March 20th was in the north-east, and it rained a little on that day; old settlers say that is the sign of a wet summer. I hope it is, for 1900 was the driest year I have ever seen. We had plenty of rain in April, 1900, to raise the wells and springs, but did not have any more to amount to anything until March, 1901, and the wells and springs were nearly all dry, but we have plenty of water now.

I hope this season will be a good one, for we have had two poor ones in succession.

JOHN H. KIRKLE,
Sussex Co., N. J., April 5.

Report for Two Years.

This year will be my third one in the bee-business. I started with one colony, and bought four more the following fall, but lost one in wintering. I had an increase of 3 colonies last season. The last of August one of the colonies became queenless, and I bought a new queen from a bee-keeper here, but the bees killed her, so I put a piece of thin wrapping-paper on the top of one of the other col-

onies, and set the queenless colony on top of it; they made holes thru the paper and are all right.

I have wintered the bees on the summer stands packed in straw, all facing the South. I have not unpacked them yet as it is cold and windy. Every warm day they are out working on apricots and wild flowers. We have a small flower here not more than 4 inches high which blooms about March 1st, and the bees get honey and pollen from the flowers. They grow as thick in some places here as do the wild strawberries in the East.

I secured 60 pounds of honey from one colony the first summer, and the second year I got 315 pounds from 4 colonies. This year I have 5 colonies, and the prospects are very good for this season.

Mrs. BEN. FERGUSON,
Ford Co., Kans., April 8.

A California Lady Bee-Keeper's Experience—Dark Beeswax.

I have kept bees for the last 5 years, and the first 3 were very good honey years, but I knew very little about the business. The year 1890 being a very poor year, I rented the bees to a man who claimed to be a scientific bee-keeper, and he divided them as long as there was anything or any bees to divide. Last year I rented them to two young men, who did the best they could with them, but the honey crop was a total failure, so they could do nothing but build up the colonies. The bees wintered all right, and are doing well. I will attend to them myself this season, hiring help when necessary. I never wear a veil or gloves, and very rarely get stung. I treat them as I do people—never go into their house without rapping, then wait for them to stick up a little before I raise the cover. I then give them a little smoke, but not enough to make them think that their house has turned into a smoke-house.

Some people seem to have a great deal of trouble with dark beeswax. I think the utensil used to melt it in has much to do with it. I have some very dark beeswax made from starters. I had about 20 frames containing starters about 2 inches wide; I wanted full sheets of foundation, so last fall I exchanged them. I put the starters into an iron kettle to

Red Clover Queens

LONG-TONGUED BEES ARE DEMANDED NOW.

ONE Untested Italian Queen FREE as a Premium for sending us TWO new subscribers to the American Bee Journal for one year (with \$2); or, one Tested Queen free as a premium for sending us FOUR new subscribers (with \$4.00.)

We have arranged with one of the oldest and best queen-breeders (having many years' experience) to rear queens for us the coming season. His bees average quite a good deal the longest tongues of any yet measured. The Breeder he will use is direct from Italy, having imported her himself. Her worker-bees are large, somewhat leather-colored, very gentle, and scarcely requiring veil or smoke. They stored red clover honey last season.

Orders for these fine, "long-reach" queens will be filled in rotation "first come, first served"—beginning about June 10th. It is expected that orders can be filled quite promptly, as a large number of nuclei will be run. All queens will be guaranteed to arrive in good condition, and all will be clip, unless otherwise ordered.

CASH PRICES of these fine queens will be as follows: Untested, \$1.00 each; Tested, \$2.00 each. Send all orders to

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

APIARY OF MRS. ARTIE BOWEN, OF MERCED CO., CALIF.

melt, and they were nice and yellow before I put them in, but after they were melted into wax I never saw such black stuff. A bee-keeper told me that he thought it was the iron kettle that did it.

My apiary is in the orchard. I had 110 col-

onies, and the apricot trees were in full bloom when the picture shown herewith was taken. The people in the picture are the two young men who had rented the apiary, and a young woman who was working for us.

I don't care for long-tongued bees. I have

no use for long-tongued women, and I am afraid they might be like them—using their tongues where they have no business to.

Fruit-trees are in full bloom, and the bees are humming.

I like the American Bee Journal very much.
(MRS.) ARTIE BOWEN.
Merced Co., Calif., March 5.

Poor Locality for Bees.

This is a bad country for bees; most of them have started to die this winter. I will have to feed mine as soon as the weather is warm enough. I have not lost any colonies yet. It is snowing every day.

JOHN BERNT.
Polk Co., Nebr., April 2.

Feeding Sugar-Candy to Bees.

On page 201 Dr. Miller asks for the experience of those who have fed candy. One winter I fed a number of colonies with candy made as per directions given in "ABC of Bee-Culture," and I am sorry to say that it was a dead failure. The candy seemed to be all right, but the bees were all dead before they were put out in the spring, with the exception of 2 or 3 colonies, and they died a few days after they were put outdoors. One such experience is enough for me. I have a suspicion that the cheapest and best way to feed in winter is to give them comb-honey—a cheap grade would do, of course. I fed it to some of my colonies during the past winter.

Hennepin Co., Minn. WM. RUSSELL.

Taxing Bees in Iowa.

I notice on page 211 you discuss the question of taxing bees. In this state the list of exemptions includes 10 colonies of bees, all poultry, and various other articles, and then says that all other personal property is taxable, which includes all bees over 10 colonies. Now, right there is the injustice—exempting 10 colonies. How would it seem to exempt 10 acres of land, 10 cows, 10 hogs, etc., all thru the list of personal property? Isn't it the same principle? Why shouldn't I pay taxes on 10 colonies as well as my neighbor on 40 or 50? And don't you suppose 10 will be about the usual number owned by the average run of bee-keepers in February or March, which is the time our assessor generally gets around? And who will pay under this law? Only those who have worked up so large a business that the public, including the assessor, would know

Best White Alfalfa or Basswood Extracted Honey

ALL IN 60-POUND TIN CANS.

ALFALFA HONEY.....

This is the famous White Extracted Honey gathered in the great Alfalfa regions of the Central West. It is a splendid honey, and nearly everybody who cares to eat honey at all can't get enough of the Alfalfa extracted.

BASSWOOD HONEY.....

This is the well-known light-colored honey gathered from the rich, nectar-laden basswood blossoms in Wisconsin. It has a stronger flavor than Alfalfa, and is preferred by those who like a distinct flavor in their honey.

A sample of either, by mail, 8 cents; samples of both, 15 cents—to pay for package and postage. By freight—one 60-pound can, 9½ cents per pound; two cans, 9 cents per pound; four or more cans, 8½ cents per pound. Cash must accompany each order. If ordering two or more cans you can have half of each kind of honey, if you so desire. The cans are boxes.

Order the Above Honey and then Sell It.

We would suggest that those bee-keepers who did not produce enough honey for their home demand this year, just order some of the above, and sell it. And others, who want to earn some money, can get this honey and work up a demand for it almost anywhere.

they had a large number of bees. Then there is poultry—all poultry is exempt from taxation in Iowa, and there are probably a hundred dollars invested in poultry to one dollar in bees; and no doubt the annual cash returns from poultry are as much, or more, in favor of the feathered tribe. So if bees are taxed as property having a first value, and are a more or less certain source of income, then by all means list poultry also.

It is evident that there are reasons for exempting property from taxation—two very good ones are, to favor the poorer classes, and to encourage some industry that is a benefit to the country in general. Now, why have not bees the very best status on both of these grounds? They are the ideal property for a poor man—not that he can make money rapidly and easily therewith, but they require little capital for a start, many successful bee-men start on nothing, even catching their first swarms as strays. And as it is generally admitted that bees are necessary to the cross-fertilizing of our fruits and flowers, and thereby a great benefit to the people in general, we can claim exemption on that ground, if any class of property can.

We are not claiming that bees are not taxable, for we believe they are in this State, but we think they ought to be exempted for the above reasons.

Personally, I have never paid any tax on bees, as our assessor never asked me to list my bees but once, and then I told him (and I think truly) that I did not know how many colonies I had at that time, as it was in February or March. I told him if he would call in May or June I could tell him how many I had. So he said he would let it go. I have no idea that there ever was a dollar tax paid on bees in this county. E. S. MILES.

Crawford Co., Iowa.

Weather Too Bad to Put Bees Out.

I put 5 colonies of bees into winter quarters, but lost one. I wish that we might have pleasanter weather so that I could put them out. It rains or snows nearly every day, but we are hoping that it will soon change.

Last season was a very poor one in this vicinity. The bees did not do much of anything, and the colony that I lost was a winter swarm which stored very little honey, so I gave it 4 combs of sealed honey and thought that would bring it thru the winter all right, but about a month ago I found it dead. There was a little honey left in the hive, and also some sealed brood, so I do not know what was the trouble. DAVID STICKY.

HONEY AND BEESWAX

MARKET QUOTATIONS.

CHICAGO, Apr. 18.—Choice grades of white comb honey sell at 10c, and there is no surplus in sight. Other grades of comb sell fairly well at the following prices: No. 1 grades of white, 14@15c; off grades, 13c; light amber, 12c; dark amber, 10@11c; buckwheat and other dark combs, 9@10c; candied and mixt combs, 7@9c. Extracted is dull, and prices very weak, with the exception of some fancyinden and clover grades, which are quoted at 7@8c; cream, 6@7c; dark and buckwheat, 5@6c. Beeswax, 30c.

R. A. BURNETT & Co.

BUFFALO, Apr. 18.—Fancy white comb, 15@16c; poor, dark, etc., 8@13c, as to grade. Demand good on fancy. Beeswax, 24@26c, as to grade. BATTERSON & Co.

OMAHA, Mar. 30.—Demand fair; stocks light. Fancy white comb, 15@16c. Extracted moving slowly at 7@8c for white. We do not look for any particular change for the balance of the season, as present supply will just about be sufficient to supply the trade until we crop gets into market. PEYCKE BROS.

DETROIT, Apr. 18.—Fancy white comb, 14@15c; No. 1, 13@14c; dark and amber, 10@12c. Extracted, white, 6@7c; amber and dark, 5@6c. Beeswax, 27@28c. M. H. HUNT & SON.

NEW YORK, March 19.—Our market is virtually bare of comb honey, and there is a fair demand for all grades. Fancy white is still selling readily at 10@11c; No. 1 white at 9@10c; 13@14c; amber at 12@13c; buckwheat, 10@11c, according to quality and style of package. As to extracted, the market is quiet and inactive, and a certain amount will have to be carried over again. Prices are declining somewhat, and if the honey is not moved in large lots, concessions will have to be made. We quote: California white, 7@7½c; light amber, 6½@7c; other grades and Southern, 6@6½c per gallon. Beeswax very firm at 28@28½c, and for exceptionally fine yellow, 29c.

HILDRETH & SEORLEN.

CINCINNATI, Apr. 18.—The demand for comb honey is nearly over. The market has been cleaned up. Fancy white brings 10 cents; extracted is in fair demand; dark sells for 7½c; better grades bring 6@7c; fancy white clover from 5½@6c. C. H. W. WEBER.

KANSAS CITY, Apr. 18.—There is very little honey offered, and the demand is steady, selling from \$3.50@\$3.90 per case, fancy white; no amber on the market at this time. Extracted, no change; white, from 8@8½c; amber, there is a little on this market that can be sold from 7½@8½c. Beeswax scarce and demand good, at 25@26c. W. R. CROMWELL PRODUCE CO., Successors to C. C. Clemens & Co.

ALBANY, N. Y., Apr. 19.—Honey market quiet. Light supply and light demand now. The stock is well cleaned out, so will be no old honey to carry over this season. H. R. WRIGHT.

BOSTON, April 4.—Fancy No. 1 white in cartons, 17c; A No. 1, 16c; No. 1, 15@16c, with a fair good demand. Amber and buckwheat, no call for dark honey this year. Extracted, white, 8@8½c; light amber, 7½@8c. Beeswax, 27c.

BLAKE, SCOTT & LEE.

SAN FRANCISCO, April 3.—White comb 12@13 cents; amber, 9@11c; dark, 6@8 cents. Extracted, white, 6@6½c; light amber 4@4½c; dark, 4@4½c. Beeswax, 26@27c.

Despite general expectations and contrary to experience of previous years, new honey is reported on the market. For some new amber extracted from Ventura county 6 cents is asked. This is above the views of buyers. Old is still offering in moderate quantity, both comb and extracted, mostly amber.

\$15.00 and \$25.00 Queens

Having a Measured Tongue Reach.

The call for queens of our celebrated \$200 imported mother
has been so great that we have decided, in addition to the \$2.00,
\$4.00, and \$6.00 grades of this stock, to offer some \$10.00, \$15.00,
and even \$25.00 of this same blood. But these prices are for tested
queens, the tongues of whose bees have been measured.

The \$10.00 queen is guaranteed to produce bees with a tongue-
measurement of 19-100.

The \$15.00 queen, 20-100.

The \$25.00 queen, 21-100.

These last are very rare and with one exception this (21-100)
is the longest tongue reach yet secured. We reserve the right,
when we do not have the stock with the tongue reach called for,
either to return the money or to send the next lower, remitting
the balance. It would be well for our friends to put in their or-
ders at once, and as soon as we get the grades we will send notice.
When the money is sent, the queens will be forwarded. These
will be put up in the very best manner possible; and while we
guarantee safe arrival in good order to any point in the United
States, on any railway line, we will not guarantee safe intro-
duction. Such valuable queens should be released on hatching
brood.

N. B.—It seems as if it ought not to be necessary to say that
no one but a queen-breeder or a large honey-producer should order
these high-priced queens; but it is a fact according to our ex-
perience that beginners with only a few colonies will order our high-
est priced imported queens. Such bee-keepers have no more use
for such queens than a pig has for a wheel-barrow.

AMERICAN BEE JOURNAL

GEORGE W. YORK,
Editor.

CHICAGO, ILL., MAY 2, 1901.

FORTY-FIRST YEAR
No. 18.

WEEKLY

MAY

BY EUGENE SECOR.

One day

I past an orchard where the bloom
Seemed coaxing honey-bees
To stop and sip its tempting wine
And pack their basket-knees
With pollen-bread on which to dine—
Both laden with perfume—
And it was May.

In May

The dandelions ply their art
To spread a honey-feast;
They fling their yellow banners out
Against the beaming East
As if to say to bees about,
"We yield our inmost heart—
Kiss us, we pray."

In May

The birds are busy building nests
Or guarding pregnant eggs:
King Corn, tho buried out of sight,
Is soon upon his legs
To prove the crown is placed aright—
For all the loyal West's
Corn-men so say.

Survey

The clover-fields, the grazing herds,
The dogwood in full flower,
The trees that stretch an inch each day
With quick'ning shine and shower.
Survey, and tell me, need I say
In stronger, ampler words,
That this is May?

Rocky Mountain Bee-Plant Seed!

(Clover integrifolia.)

...FREE AS A PREMIUM...

The A. B. C. of Bee-Culture says of it: "This is a beautiful plant for the flower-garden; it says nothing of the honey it produces. It grows from two to three feet in height and bears large, clusters of bright pink flowers. It grows naturally on the Rocky Mountains, and in Colorado, where it is said to furnish large quantities of honey."

We have a few pounds of this Clover seed, and offer to mail a ½-pound package as a premium for sending us ONE NEW subscriber to the American Bee Journal, with \$1.00; or ¼ pound by mail for 40 cents.

GEORGE W. YORK & CO.

144 & 146 Erie St., CHICAGO, ILL.

The Emerson Binder.

This Emerson stiff-board Binder with back hock for the American Bee Journal we mail for but 60 cents; or we will send it with the Bee Journal for one year—both for only \$1.40. It is a fine thing to preserve the copies of the Journal as fast as they are received. If you have this "Emerson" no further binding is necessary.

GEORGE W. YORK & CO.,

144 & 146 Erie Street, CHICAGO, ILL.

..... WE WANT

1,000 NEW Subscribers

During May and June.

We want
We want
We want

500 of our present regular subscribers, whose subscriptions are now paid in advance, to help us get the 1,000 NEW SUBSCRIBERS.

each one of you to get just TWO new subscribers, and the job will be done? See?

to ask you to get them only for the rest of this year—to the end of 1901. And the price will be but FIFTY CENTS EACH—or \$1.00 for the two new subscriptions.

G. M. DOOLITTLE.

We want to offer to each one who sends us 2 new subscribers on the above condition, a copy of

DOOLITTLE'S

"Scientific Queen-Rearing," free.

We have just issued a New Premium Edition of this fine book, bound in leatherette cover, with round corners. It is in every way (excepting just the cover) the same as the cloth-bound edition. This is

A MAGNIFICENT OFFER,

and every one of our paid-in-advance subscribers who has not already a copy of Doolittle's "SCIENTIFIC QUEEN-REARING," ought to jump at this generous offer.

Remember, it is only for May and June that we are making the above offer, so you'd better

be quick about it if you want a copy on the easy terms mentioned—for sending us only two new subscribers to the Bee Journal at 50 cents each, for the balance of this year, beginning as soon as their subscriptions are received here with the \$1.00 to pay for them.

Doolittle's "SCIENTIFIC QUEEN-REARING" has 128 pages, and describes the "method by which the best of queen-bees are reared in perfect accord with Nature's way. For the amateur and veteran in bee-keeping." It also contains Mr. Doolittle's management of bees for the production and care of comb honey. Every bee-keeper should have a copy of this book.

The Books are Now Ready to Mail.

Will you be one of the 500 to have a copy of it on the above premium offer? If so, your answer will come soon with the \$1.00 and the names of two new subscribers.

If You Have Doolittle's Book,

you can choose ONE of the following instead as a premium (postpaid) for sending the two 50-cent subscriptions:

1. Two Porter Bee-Escapes.
2. A No. 3 Bee-Veil, made of all cotton tulle.
3. Parker Foundation Fastener for sections.
4. Spur Wire Imbedder and Cogshall Bee-Brush.
5. Cogshall Bee-Brush and Carlin Comb-Foundation Cutter.
6. Carlin Cutter and Spur Imbedder.

The foregoing offers will not appear again. They will be in force only during May and June—this month and next.

Now for the 1,000 New Subscribers!

Address, GEORGE W. YORK & CO.,

* Editorial. *

Next National Convention.—It seems from the following, sent us by Secretary Mason, the next meeting of the National Beekeepers' Association will be held at Buffalo, N. Y., Sept. 10, 11 and 12, 1901:

EDITOR AMERICAN BEE JOURNAL:
Many inquiries have been received by the Executive Committee of the National Beekeepers' Association regarding the time and place for holding the next convention. The reply has generally been that Buffalo, N. Y., would be the place of meeting; but until this morning (April 17th) the date of meeting had not been settled upon.

On March 24 the Secretary of the American Pomological Society wrote President Root in part as follows:

"As bee-keepers and fruit-growers have many interests in common which could be considered and discussed with mutual profit, our Executive Committee has instructed me to extend to your Association a cordial invitation to hold a joint meeting at some time during our session, the exact time to be decided later by correspondence.

"At this meeting we would suggest that the subjects of discussion center round the general topic of the mutual relations of bee-keeping and fruit-growing..... which can be briefly treated by speakers selected in advance from among our prominent bee-men and fruit-men..... in order that a better understanding of these mutual relations may be reached.

"..... It has been suggested that a considerable portion of fruit-growers do not yet appreciate the preponderance of the benefit derived. It is felt that a full public discussion of the subject would, therefore, result in good to both industries."

Realizing, as the Executive Committee did, that this was a golden opportunity for presenting the bee-keepers' side of the subject to the representative men of the fruit-growing industry, the invitation of the Pomological Society was at once accepted by the committee in behalf of the Association.

We have had to delay the fixing of the date for our convention until the Pomological Society had fixed their time of meeting. Our convention will be held on the 10th, 11th, and 12th of September next, commencing on Tuesday evening the 10th.

We were at first undecided as to place of meeting, hoping that the G. A. R. would meet at Denver, Colo., but when it decided to meet at Cleveland, and we received the invitation of the Pomological Society, we felt that we ought not to miss such a splendid chance to enlighten some of them on the relation of bees to horticulture, and by meeting at Buffalo, the York State and Canadian bee-keepers would be within easy reach of the place of meeting; so we at once fixed on Buffalo as the most desirable place.

It has been decided not to have any papers or essays, but to rely wholly on the question-box to bring out the best and most important matters for discussion, so any one not being able to be at the convention, having any question or questions that he may wish to have

discussed, can send them to the Secretary at any time.

The committee has taken the liberty to request the Secretary of the Ontario Beekeepers' Association to ask the members of that association who may attend the meeting at Buffalo, to bring their badges with them and wear them at our sessions, whether they are members of our Association or not, so that we may feel more as one, and know who our progressive neighbors are.

Information regarding place of meeting, entertainment, and railroad rates, will be given as soon as decided upon. Don't be in a hurry about securing a sleeping-place during the convention. There is plenty of time, and later on, better rates can be secured; but if you are in a hurry, write to the Young Men's Christian Association, and don't be misled by "sharks."

A. B. MASON, Sec.

Sta. B, Toledo, Ohio.

We trust that all who can possibly arrange to do so will endeavor to be at the Buffalo convention next September. It ought to be a bigger and better one than was the Chicago convention last August—tho, of course, that could hardly be expected even at Buffalo! (Now, see Mr. Hershiser buckle down to the job of trying to outdo Chicago.)

"There is Always Plenty of honey."
said a honey commission dealer to us several years ago. That seemed a strange remark to make, especially in view of what have commonly been termed "poor honey-years," which have been somewhat frequent in appearance during the past ten or fifteen years. But Mr. Dealer knew what he was talking about.

The year 1900 was said by some, if not by the "oldest (bee-keeping) inhabitant," to have been the poorest for honey in thirty years. And yet what do we find? Why, more honey in the hands of dealers to be carried over, we believe, than for a number of years past. One dealer, about two months ago, had eight or ten car-loads of white extracted honey on hand yet. We know some others who also have quite a quantity left on their hands. Likely all of them will have to wait until next fall before it can be moved off; and then, if there should be a large new crop, it will have to be sold at a loss.

"There is always plenty of honey" comes pretty near being the truth. But it would not be true if there were anything like a more even distribution of the honey crop each year. Why, there wouldn't begin to be enough to go half way around if that were the case. The great trouble is, so much of it is shipped to the large centers, thus glutting those markets, causing a demoralization of prices, while many near-by, the smaller, markets, are entirely bare of honey. And often in such local markets the very highest prices are realized.

In a city of about 2,500 population, not quite a hundred miles away from Chicago, a

leading grocer agreed to take as high as five car-loads of strawberries grown within 15 miles of his store, at 10 cents a quart! Think of it! And yet, in Chicago strawberries are often sold at four quarts for 25 cents! Why is it? Simply because nearly every strawberry-grower in the country thinks he must dump his crop on the Chicago market. It is all wrong. And it is the same way with honey.

Far better prices would be secured if much of the stuff that is sent to Chicago, or to other large centers, were sold nearer home. This is a subject worth careful investigation.

Short-Tubed Clover is nowadays discussed along with long-tongued bees, and it is reasonable to believe that the seed saved from the first crop of red clover will have in it a larger percent of the short-tubed kind than that from the second crop. A little explanation will help to an understanding. At present it is only the second crop of red clover that is a seed crop. That is because the fertilization of the blossoms is effected almost entirely by bumble-bees, and at the time of the first crop there are not enough bumble-bees to fertilize more than a very small number of blossoms. For unlike hive-bees, a single bumble-bee starts a nest in spring, and only later on do bumble-bees appear in numbers.

So it happens that the proportion of hive-bees to bumble-bees found working on the first crop should be many times greater than on the second. It will be only the shorter-tubed kind that the hive-bees will visit, of course, and the seed from that will be likely to reproduce itself. It will be easily understood that at first only a small amount of seed would be secured on any given surface, but the proportion ought rapidly to increase from year to year. It may be well to speculate a little on what might be the outcome. Suppose we take a plot of ground from which a bushel of seed of the second crop might be secured. Save the seed from the first crop, which may be a pint or less. But in that pint half the seed may be of the short-tubed kind, whereas in the second crop there would not be one in a thousand. Now sow this pint the next year in a plot by itself. It is reasonable to expect that at least half the plants will have short tubes, and so half the seed will be of the improved kind. Continuing in this way, it would be not a matter of many years to have seed in unlimited quantity, half of which would be of the short-tubed kind.

But another factor comes into the problem, which greatly hastens the result. As soon as the amount of ground covered by clover from this half-and-half seed assumes tolerable proportions, the seed fertilized by bumble-bees

will no longer hold the same proportion as at first. For the number of bumble-bees is a limited quantity, and they can only fertilize a fixed number of flowers. For the sake of illustration suppose there are enough bumble-bees to produce a bushel of seed within a given area. A small field will suffice then, and if the field be ten times as large they can fertilize no more seed. Now suppose enough of our half-and-half seed is sown in that area to produce two bushels of first-crop seed. It will continue to be half-and-half just so long as we do not go beyond that amount. But whenever we go beyond the crop of two bushels, then not only a proportion of the increase, but *all* the increase should be short-tailed.

If a peck of seed is sown to the acre, and the crop harvested is three bushels to the acre, then there is a twelve-fold increase. So when our bushel of half-and-half seed produces a crop of 12 bushels, 11 bushels of it ought to be of the short-tailed kind, and this 12 bushels sown ought to produce 144 bushels having only one bushel of long-tailed seed in it, or 99.3 percent pure. "It is the first step that costs," and in this case the difficult thing is to get the first bushel of half-and-half seed. After that the way is easy. Indeed the way ought not be very hard after the first pound is secured.

Of course, all this is only speculative, and like many another thing in bee-keeping, may not "pan out" at all as anticipated; but the great importance of the matter warrants some speculation, and this may serve at least to arrest the thought of some wide-awake bee-keeping farmer, and to secure from him some effort toward the desired end.

Loading Combs for Wagon-Hauling

The right way to load combs, either brood-combs or sections, has been a matter of some difference of opinion. When loaded on cars, all seem to agree that the edges of the combs should point toward the engine, as the bumping is from front or rear, and not sidewise. Opinion is divided as to loading on a wagon. Perhaps all will agree that on a smooth road on a very steep hill the loading should be the same as on a car, but ordinary roads are not so very smooth, and the hills are not so very steep. The editor of the Bee-Keepers' Review champions loading the same as on a car, and gives reasons why he thinks that ought to be the better way. A few have given the result of actual experiment, one of which is given in a *Stray Straw* in *Gleanings in Bee-Culture* as follows:

March 25th the roads were muddy and rough. I drove down town, putting in the wagon two empty supers, setting them on one side. The front one ran across the wagon and the other lengthwise. The one running lengthwise fell down. Then I put the front one lengthwise and the other crosswise. As often as they fell I set them up again, constantly changing. Out of 13 times the lengthwise super fell first every time but one. That was going down a hill, but going down the steepest hill the lengthwise super fell and the other stood its ground. If I had been hauling combs on that trip, don't you believe they should have been loaded crosswise? Now some of you report how the same thing works on *good* roads. [This is an interesting and valuable experiment. It is so easily tried that wonder none of us had thought of it before.] would suggest that those of our readers who have to drive to town pretty often overumpy roads, try the same experiment and

report. From the results above given it is very clear that the edges of the combs should point toward the wheels and not toward the horse.—EDITOR.]

Bees Attack Mountain Climbers—

A correspondent from Honolulu, Sandwich Islands, reported an occurrence in that country in which a mountain-climbing party was attacked by a colony of wild bees, and came near losing their lives. They had climbed Konaohuahi, the highest peak near the city, and decided to descend on the Nuamu Valley side, which had been considered impossible. They scrambled down precipitous cliffs 75 feet high, clinging to the rocks with hands and feet. When part way down they were attacked by the bees, which stung them while they were helpless to ward them off. For nearly a mile the bees followed them until they reached a point where they were safe.

Weekly Budget.

GOOD ADVICE [For Missouri?].

"Pray, what is good for chappy cheeks?"

Wrote Molly to the editor,

And in due time—about two weeks—

She got the answer written for.

To other ears by chance it leaks,

A little birdie told, perhaps;

Thus: "If you wish not chappy cheeks,

You must avoid the cheezy chap."

—WILL WARD MITCHELL.

MR. JOHN ZWAHLEN, of Emery Co., Utah, gives the following report for 1900, in the Rocky Mountain Bee Journal, being an average of 292 pounds of extracted honey per colony:

"I see it stated that Oliver Foster produced 80,000 pounds of honey last year from 500 colonies. I have done better than that. I secured 19,000 pounds from 65 colonies; and Christian Ottsen, 23 miles farther north, in this county, did even better, but I can not say just how much."

"EDITOR MITCHELL, who undertook part of the editorship of this paper last autumn, has been compelled to abandon the undertaking. His eyes for the past year or two have been of more or less trouble, and of consequent great distress—to one who has to use his eyes almost continually, as does a printer and editor."

This paragraph is taken from the April Progressive Bee-Keeper. We regret very much to learn that Mr. Mitchell's affliction has compelled him to relinquish some of his undertakings, and trust that the enforced rest and recuperation may soon bring him out all right.

PRESIDENT E. S. LOVESY, of the Utah Bee-Keepers' Association, writing us from Salt Lake Co., March 12th, had this to say:

"FRIEND YORK: Spring appears to be with us again. The bees, the trees, and the birds, in fact all Nature seems to be putting on new life. Our bees were carrying in pollen March 1st—something they don't often do so early. And we are having a great deal of snow and rain, which is pretty generally distributed over the state, thus insuring a good supply of irrigating water, which in turn will

insure good crops and a good honey-flow. If the weather keeps mild we may expect to see our bees and bee-keepers 'in clover' once again. The bees that went into winter quarters in good condition appear to have withered fairly well, while a few smothered for lack of ventilation. The smelter smoke here in Salt Lake County has been the cause of our principal losses."

Again on April 14th Mr. Lovesy wrote us as follows:

"The prospects are excellent in Utah this season for a good honey crop. While the bees are in fairly good condition, barring any accident that we know not of, they will give a good account of themselves."

EDITOR LEAHY, of the Progressive Bee-Keeper, it seems, was also somewhat shocked by the "rhythmic break" made by Steng in *Gleanings in Bee-Culture*, when he tried to make "harm" rhyme with "barn." After copying the questionable stanza (see page 244), Mr. Leahy follows with this comment:

It's rather a stretch of poetic license, and tho we are quite willing the price of clover be brought down, we are not willing to see the harmony of "harm" and "barn." The following from the pencil of a despondent Ohio youth has more jingle and rhyme, and is more to the point:

"O, bury me deep, deep in the ground,

Where the humming-bird hums.

And the bumble-bee hums,

And the straddle-bug straddles around."

We must confess that Mr. Leahy's cultivated choice of poetry does have a clear-cut kind of jingle that no one can mistake or fail to appreciate. In the "hum" and the "bum" of the thing there is no humming poetry, even if there is a straddle-bug that "straddles around" with so much importance.

MR. W. F. ORDETX, of Cuba, under date of Jan. 23d, says that the present season has been the poorest ever known in that section, and concludes the information with this paragraph: "I started with 8 colonies in December, and now have 20. They will soon be ready to drive again." No doubt that report is rather discouraging to one of Mr. Ordetx's enthusiasts; but he would be surprised to learn how very little sympathy is felt in these United States of America, where almost any of us should consider ourselves very fortunate to accomplish in two whole years what he has done in two months or less. That projected second division of colonies so late in the season may prove a hazardous procedure.—American Bee-Keeper.

MR. A. E. WILLIOTT, of Hampshire Co., Mass., sent us a clipping some time ago telling about a "happensence" down in Bangor, Maine, last fall. It seems when cold weather set in a fire was kindled in a fireplace in one of the houses in that city, that had not been occupied for some time. When the fire had been burning for about half an hour, the man of the house, upon coming into the room, found the floor covered with a sticky substance, more of which was running out of the fireplace. It was found that a swarm of bees had taken up their abode in the long unused chimney, and had there stored a large quantity of honey. The heat from the fire caused it to run down in a stream into the room, covering the carpet. The householder said he got 84 worth of honey and lost \$50 worth of carpet. He probably did not feel like singing that part of the chorus of the song, "Busy, Buzzy Bees," where it refers to "honey everywhere."

No. 3.—Drone-Bees and Their Utility.

Can We, and Shall We, Control their Production?

BY C. P. DADANT.

SINCE writing the two previous articles on this subject, I have met with some private arguments. I have been told that it is a mistake to try to change Nature, that even if I can reasonably argue that it is best to prevent the rearing of drones in most circumstances, it is an error to change natural conditions. I can not agree with this.

When we breed any kind of animals in domesticity, their natural conditions are already changed. No one thinks of trying to prevent the free breeding of wild fowls in the proportions which Nature has dictated. But where is the breeder of domestic fowls who will allow all the roosters to live? Where is the farmer who will keep all his male calves as bulls? And do we not succeed best by artificial selection? See with what care the farmer's wife picks out the finest roosters for the following season's use. And if she were careless, and killed or sent to market the finest of them, would you think she stood any chance of improving the breed? What is done with chickens or with cattle—can it not be done with our bees, in the measure of our powers? It is true that we can not absolutely control the reproduction, owing to the peculiar habits of the bees in their mating, but we can, in a great measure, direct the greater or less rearing of good or bad stock, and if we would succeed, we must do all that can possibly be done.

In natural conditions, a colony may be several miles from other bees and probably requires all the drones that it may produce. On the other hand, in domesticity, we may keep a hundred or more colonies in one spot. In that case, we have, if we leave it to the nature of the bees, a hundred or more times as many drones as will be needed for all the young queens that we may rear. We are therefore feeding, if we leave the bees alone, hundreds of thousands of drones that cost both food and heat to be reared, and whose problematic usefulness is in the possibility of their keeping the brood warm for a few days after the colony swarms. Some of these drones are certainly more desirable than others, for our colonies are not all equal in honey-production. In an apiary of one hundred colonies, we may have half a dozen colonies which will yield twice or three times as much honey as the average of the entire apiary, and at the same time we have a few colonies that will produce little if any more than enough for their own consumption. Not only must our female reproducers—the queens—be reared from some of those best colonies, but if we would encourage in all possible ways the breeding of the best, we must also try to breed the greatest number of drones from some of those preferable colonies. Yet, to avoid in-and-in breeding, which Nature so abhors, we should not breed both queens and drones from the same colonies.

These propositions being well established, it remains for us to decide not only how to get the greatest possible number of drones from the best colonies, but also how to prevent the fertilization of the queens by inferior drones.

Let me here open a parenthesis. I see that the question of the fertilization of queens in confinement is again agitated. If this were a success the fertilization of queens would be comparatively easy. But these things have been tried many times before, many sensible men have shouted "Victory!" only to find a little later on that they had allowed themselves to be deceived by appearances. Time will settle the question, but even a satisfactory solution would not affect the question of producing valuable drones and doing away with the valueless ones. I will now return to the matter on hand.

To secure a great number of drones from a colony is not difficult, especially if the queen is prolific. We need but to place drone-combs, one or two, in the center of the brood-nest. Altho the queen dislikes to lay eggs in these cells, until after she has bred a large number of workers, the situation of these combs will induce her to lay in them earlier in the season than she would have done otherwise,

and we will readily secure a large number of valuable drones early. As to the hive from which no reproduction is desirable, we must confine the drones to the hive, or catch them with a drone-trap as they emerge on sunny days, or behead them in the cells before they hatch, or simply prevent their being produced by removing the drone-comb before the laying has begun, and replacing it with worker-combs.

The first of these methods is certainly the worst. Many apiarists use the well-known drone-guard in front of the hive. This is a sort of "yard" made of perforated zinc placed at the entrance, and thru which the worker-bees alone can pass. The drones and the queen are compelled to stay in. It is also used to prevent swarming. Tho it answers the purpose, it is not practical because when the drones are induced to take flight by the warmth of the sun, they congregate within this guard and are in the way of the bees. Some people open the guard to let the drones out, and close it again to keep them from coming back. It would serve the purpose in compelling them to stay on the outside and starve if they were all to issue at the same time, but they are going and coming, and no satisfaction can be had out of such a method. The drone-trap is much better, for as the drones get into it they are caught and can not return, and are out of the way, but it must be attended to and emptied out regularly or they will die there and create a pestilence.

The third method, of beheading the sealed drones with a honey-knife, before they hatch, is efficient, but like the other two it has the very bad fault of having allowed the expense of rearing those drones almost to the perfect insect, without any returns. Then the comb in which they have been reared is very soon again filled with eggs, and the work must be done again. The last and only practical method of getting rid of the drones satisfactorily is to prevent their being reared, by removing the drone-comb before any drone-eggs are laid, very early in the spring, and replacing this comb with worker-comb, taken from decessant colonies or from extracting supers. This replacing of comb is a necessity, for the same reason that has caused the bees to build the drone-comb in the first place will cause them to rebuild the same kind in the same spot, if they are allowed to do so. But it is useless to expect to be able to remove every cell of drone-comb. In nearly every hive there are quite a number of little patches of drone-cells scattered here and there, and many of these pass unnoticed even on the closest examination, unless they are already full of brood, in which case the peculiar rounding shape of the capping of the drones will make them noticeable. But the production of a few drones in any hive is not objectionable. It is the pieces of six or eight inches square that give us the hosts of useless males, since the comb contains 36 of them to the square inch.

In my estimation, the prevention of drone-rearing is of importance especially because of the cost of breeding them. I have always been of the opinion that they are nearly as expensive to rear as they are to keep after they have hatched. Yet, they certainly consume considerable honey after they have emerged from their cell, but I would be inclined to think that nearly half of the total cost of their support during their short life is to be reckoned while they are in the cell. So it seems to me of the greatest importance, on this score alone, to prevent their being hatched.

I am told that the bees will not accept the removal of their drone-comb, and that they will cut down worker-cells, to change them to drone-comb, when all the drone-comb has been removed. This I disbelieve, as it is contrary to my experience. Tho they will rebuild drone-comb where drone-comb has been removed, they do not seem to feel the need of it enough to tear down good worker-comb. In order to convince me that this has ever been done by bees, it would require a very thoro experiment, made on old combs that would not sag under the weight of honey. I believe that what has led some bee-keepers to this opinion is the sagging and consequent elongating of cells by heat. This sometimes happens when the comb is new and heavily loaded, or by the use of defective foundation, which by stretching has become large enough for drones to hatch in it. But I doubt that bees have ever seen fit to tear down worker-comb to build drone-comb in its place. If they were prone to do so, they very probably would be inclined to do the reverse where too much drone-comb existed, and in the case of the Drory experiment, mentioned by me in a former article, when a colony had been furnished with nothing but drone-comb, they certainly would have torn down some of this comb to replace it with worker-comb, while

they only reduced the size of the cells by narrowing them down at the mouth.

But even take it for granted that the bees will insist on having some drone-comb. We have seen elsewhere that the average number of drones produced, ranges, according to some of the most experienced writers, from one-tenth to one-thirtieth. If we can keep the average number of drones produced by our poorest colonies at or below the smallest percentage, and if we can at the same time keep the drones reared by two or three of our best colonies at the very highest possible number, we already will have achieved a great deal towards securing improved matings and a greater production of honey.

Hancock Co., Ill.

Prof. Cook's Review of the "A B C" Book.

BY ERNEST R. ROOT.

IN the columns of the American Bee Journal Prof. Cook has given a review of "Dadant's Laugstroth" and "Cowan's Honey-Bee," and now follows with a review of the "A B C of Bee-Culture." In his usual kindly manner he says at the outset, "Without doubt this book has exerted a wider influence upon the bee-keeping world than any others ever written. Even its rivals can only be joyous in its extensive sale, as they know that, wherever it goes, it goes to help and bless." Coming as those words do from one who is himself the author and publisher of a leading rival work, the publishers of the "A B C" would be hardly human if they did not feel a warming of the heart at their utterance.

He then proceeds to point out passages in which he thinks he has reason to believe there is error, altho admitting the possibility that in some cases he may be wrong. Some of these may properly deserve consideration and correction: in others there may be occasion to take exception to Prof. Cook's exceptions.

First, it is proper to call attention to the fact that the criticisms are not based on the edition issued last January, as one would suppose, but on the *old* edition—the one put out nearly two years ago. As it is, much that Prof. Cook criticises is not in the new book at all, such matter having been re-written or stricken out altogether.

As to the first error pointed out, there is no error in the book, but the error consists in very careless reading on the part of the reviewer—a carelessness that is hardly excusable, for one expects extreme carefulness on the part of one who points out the errors of others. The "A B C," page 2, in discussing what is to be done with second swarms that issue, says in effect that they must be watched, climbed after, and hived. This sentence is *immediately* followed by another which says, "If one thinks this too much trouble, he should prevent having after-swarms as I advise under that head." He ignores the fact that the watching and climbing refers only to swarms that *have* issued, to say nothing of the fact that it would be an impossibility to prevent the issuing of a swarm after the swarm has actually issued. He goes on to give the Heddon as the best method of preventing second swarms. In the edition just out of the press the very next sentence refers to the place where, among other methods of preventing after-swarms, the Heddon plan is given more fully and correctly than it is given by the reviewer. If careless reading is inexcusable on the part of a critic, still less is careless quotation when the exact words are pretended to be given inside quotation-marks. In answer to the question as to what shall be done with a second swarm that has issued, the "A B C" says, "Candidly, I don't know of any better way than," etc. "Candidly, I don't know any better way to prevent second swarms than," etc., is the way Prof. Cook quotes it. We feel sure that he will say there is no sufficient excuse for interjecting the words "to prevent second swarms" in a direct quotation where they were neither written nor thought by the author of the book.

Prof. Cook objects to the statement that alfalfa honey is probably superior in quality to any other. He claims to be something of a judge of honey, and thinks alfalfa no better than clover, linden, sage, and perhaps others. It is a matter, not of judgment, but of taste. The best judge *might* prefer a flavor that no one else would fancy. The criticism, however, is a valid one. In matters which appeal entirely to taste, it is unwise to make sweeping statements.

Speaking of alfalfa the "A B C" says it takes about three years to get it to its best yield. Prof. Cook makes

the pleasant correction that in California the maximum yield is often got the very first year in the later cuttings.

The reviewer thinks it is putting it too strong to hint that bees gather from the dry hay. The simple truth is told that "one man reports so much sweet in it that he has seen bees by the thousand working on the dry hay in the spring."

Speaking of this matter, Prof. Cook says, "This is putting it altogether too strong. Still, I do not think that too much can be said in favor of alfalfa, for it is a marvelous crop." The good Professor will probably indulge in a quiet smile when he sees these two sentences side by side: "You are saying altogether too much for alfalfa," and "You can not say too much for alfalfa." Which is one to believe?

Prof. Cook objects to the definition of digestion given by the author, saying, "This is given as a question [what can be meant by that?], but he was not happy in his selection of authority." Not all will agree as to this, seeing the authority selected was no less than the able and careful T. W. Cowan. Prof. Cook teaches that "digestion is rendering the food osmotic."

Our reviewer says "malpighian" should be "malpighian." So it is in the latest edition, and one would hardly suppose an older edition should be the one reviewed. But his correction needs further correction, neither the book nor the critic being right, for "malpighian" should be "Malpighian."
